ANNOTATED BIBLIOGRAPHY

Achenbach, T. M. (1991). *Integrative guide for the 1991 CBCL/4–18, YSR, and TRF profiles.* Burlington, VT: University of Vermont, Department of Psychiatry.
Describes relations among instruments for obtaining parent ratings, self-ratings, and teacher ratings of children's and adolescents' competencies and problems. Early chapters describe relations among the 1991 profiles of the Child Behavior Checklist (CBCL) for ages 4 to 18, Youth Self-Report (YSR), and Teacher's Report Form (TRF), including procedures for deriving empirically based syndromes common to all three instruments. Later chapters present research and practical applications for coordinating assessment of children and adolescents from multiple data sources. A good resource for users of the CBCL, YSR, and TRF for multimethod assessment.

Breen, M., & Fiedler, C. (1994). *Behavioral approach to the assessment of emotionally disturbed youth: A handbook for school-based practitioners.* Austin, TX: Pro-Ed.
Describes behaviorally oriented procedures for assessing children's emotional and behavioral disorders. Early chapters address theoretical and legal requirements for school-based assessment of emotional and behavioral disorders, including eligibility for special education services. Later chapters cover empirically based behavioral rating scales; direct observation methods; parent teacher, and child interviews; and consultation strategies. A comprehensive and practical resource for school-based practitioners involved in assessment and programming for children with emotional and behavioral problems.

Hughes, J. N., & Baker, D. B. (1990). *The clinical child interview.* New York: Guilford.
Describes various procedures for interviewing children and adolescents for clinical and school-based assessments. Early chapters cover developmentally sensitive interviewing techniques for children of varying ages. Later chapters describe different interviewing procedures, including structured diagnostic interviews, psychodynamic approaches, behavioral interviewing, and problem-specific interviews. An excellent resource for school-based practitioners and clinicians involved in child assessment and therapy.

Knoff, H. M. (Ed.). (1986). *The assessment of child and adolescent personality.* New York: Guilford.
Describes procedures for assessing personality and emotional and behavioral problems of children and adolescents. Early chapters address theoretical bases underlying the assessment process. Later chapters cover development and administration of various tests and procedures, including behaviorally oriented assessment, personality measures, and projective techniques. A pragmatic, applied view of assessment of emotional and behavioral disorders and personality in school and community settings.

Best Practices in School Reintegration

George Peabody College of Vanderbilt University

OVERVIEW

During the past 5 years, special educators have engaged in rancorous debate about what is wrong with the field and how best to fix it. Although the controversy has appeared wide ranging, including such diverse topics as tests, labels of exceptionality, accountability, fragmentation of services, and teacher referrals, it has pivoted on a basic issue: Should special education abolish or conserve the cascade of services? This question creates a meaningful divide among the major players in the debate, producing *conservationists* and *abolitionists* (see D. Fuchs & L. S. Fuchs, 1991; D. Fuchs & L. S. Fuchs, in press; and Figure 1).

Conservationists versus Abolitionists

Conservationists. By definition, conservationists support the preservation of the cascade (see, for example, Kauffman, Gerber, & Semmel, 1988; Keogh, 1988; Lieberman, 1985; National Education Association, 1992; Singer, 1988). They do so because they believe it represents a rich array of placement options necessary for schools to meet the wide-ranging cognitive, behavioral, social, and physical needs of its students with disabilities. Moreover, the degree of many students' disabilities, such as those with severe behavior disorders, requires unique and intensive support. This help, say the conservationists, often can be delivered more efficiently and effectively in settings separate from the mainstream (e.g., Kauffman, 1989; Walker & Bullis, 1991). And if too few special-needs students move up the cascade, it is not the fault of the model; rather, it is the responsibility of those who use it incorrectly.

As reflected in Figure 1, we distinguish between mild and strong conservationists. Mild conservationists (e.g., Gottlieb, Alter, & Gottlieb, 1991) differ from strong conservationists on at least two related counts: First, they are more likely to call attention to special education problems; second, they have a penchant for issuing strident calls for reforms (which, nevertheless, presume a continuation of the cascade of services).

Abolitionists. At loggerheads with both mild and strong conservationists are abolitionists who argue that increasing numbers of children in special education are proof that the cascade model is unworkable, that it represents a trap for most students with disabilities, whereby initial placements become terminal assignments in their educational careers (e.g., Taylor, 1988). Abolitionists and The Association for Persons with Severe Handicaps, the organization with which they are most closely connected, work to eliminate the cascade and for the immediate integration, or "full inclusion," of all students with disabilities into regular classrooms (e.g., Biklen, Lehr, Searl, & Taylor, 1987; Giangreco, Dennis, Cloninger, Edelman, & Schattman, 1993; Lipsky & Gartner, 1989; S. Stainback & W. Stainback, 1992; Thousand & Villa, 1990; York & Vandercook, 1991). Facilitating full inclusion would be support staff (e.g., physical therapists, speech clinicians, vocational instructors) bought with savings realized through an elimination of the cascade's special settings. Abolitionist optimism over this ambitious, if not revolutionary, plan is based on a belief that much of special education is expendable because regular education has become more expandable, that is, more willing and able to accommodate greater student diversity, including the integration of all students with disabilities (e.g., Lipsky & Gartner, 1991).

Like the conservationists, abolitionists can also claim a kindred group that espouses a milder doctrine. Mild abolitionists like Gersten and Woodward (1990), Maheady and Algozzine (1991), Pugach and Lilly (1984), Reynolds, Wang, and Walberg (1987), and Will (1986) tend to focus their criticism of special education on services provided students with milder disabilities. Reynolds (1991), for example, argues that

FIGURE 1. Continuum of opinion regarding the cascade of special education services.

ABOLITIONISTS

Strong

- The Assn. for Persons with Severe Handicaps (1992)
- Biklen, Lehr, Searl, & Taylor (1987)
- Gartner & Lipsky (1989)
- Giangreco, Dennis, Cloninger, Edelman, & Schattman (1993)
- Gilhool (1989)
- Lipsky & Gartner (1989)
- National Assn. of State Boards of Education (1992)
- Sapon-Shevin (1988)
- Snell (1991)
- Stainback & Stainback (1992)
- Taylor (1988)
- Thousand & Villa (1990)
- York & Vandercook (1991)

Mild

- Dunn (1968)
- Gartner & Lipsky (1987)
- Gersten & Woodward (1990)
- Jenkins, Pious, & Peterson (1988)
- Maheady & Algozzine (1991)
- Pugach & Lilly (1984)
- Reynolds, Wang, & Walberg (1987)
- Stainback & Stainback (1984)
- Stainback & Stainback (1985)
- Will (1986)

CONSERVATIONISTS

Mild

- California Teachers Assn. (1990)
- Council for Exceptional Children (1993)
- Deno (1970)
- Gottlieb, Alter, & Gottlieb (1991)
- New Jersey Education Assn. (1991)
- Pugach & Raths (1987)

Strong

- Braaten, Kauffman, Braaten, Polsgrove, & Nelson (1988)
- Commission on the Education of the Deaf (1988)
- Council for Children with Behavioral Disorders (198)
- Hallahan, Keller, McKinney, Lloyd, & Bryan (1988)
- Illinois State Board of Education (1990)
- International Reading Assn. (1986)
- Iowa State Education Assn. (n.d.)
- Kauffman, Gerber, & Semmel (1988)
- Keogh (1988)
- Learning Disabilities Assn. (1993)
- Lerner (1987)
- Lieberman (1985)
- McKinney & Hocutt (1988)
- Megivern (1987–88)
- National Education Assn. (1992)
- National Joint Committee on Learning Disabilities (1993)
- Singer (1988)
- Vergason & Anderegg (1989)
- Walker & Bullis (1991)

categorical approaches to the education of such children cannot be justified, whereas he implies elsewhere (e.g., Reynolds, 1988) that they are justified for children with more severe disabilities. In other words, mild abolitionists tend to push for a partial rollback of the cascade of services, not a total elimination of all special education placement options.

Reintegration: Case-by-Case and Large-Scale

Case-by-case. Although conservationists and abolitionists agree that integration, or inclusion, is an important goal, they disagree fundamentally about what rightly should be called integration and how one best accomplishes it. For conservationists, the targeted integration setting may be the mainstream, but it also may be a self-contained class for a student currently attending a special day school. Implicit is a belief that mainstreaming — reintegration into regular classes — is not necessarily for all students with disabilities.

For some, say the conservationists, an appropriate education must be delivered by a specially trained teacher in a setting removed and different from regular education, a setting where students presumably receive intensive, systematic, and data-based instruction unattainable in regular education. Many conservationists believe in a case-by-case approach to integration, by which movement up the cascade of services into a less restrictive setting, or reintegration into a regular classroom, is planned, implemented, and evaluated individually — on a case-by-case basis. Each student's strengths and weaknesses are considered in conjunction with various features of the student's future setting. A fit or match is explored. And a child is not reintegrated unless he or she can adapt academically, behaviorally, and otherwise to the expectations in the new setting. Advocates of a case-by-case approach see its individualized nature as the embodiment of that which is quintessentially special about special education and as consonant with federal law, which requires the provision of individualized educational programs (see Huefner, 1994).

Large-scale. In contrast to the conservationists' case-by-case strategy, the abolitionists' large-scale approach calls for large groups, or literally all students, to be reintegrated simultaneously into nothing short of regular education settings. Implicit is the view that it is not the child that needs to be changed, but rather the mainstream setting. Such change may involve adoption of cooperative learning structures or more sweeping arrangements like open-classroom, constructivist approaches to teaching and learning (see S. Stainback & W. Stainback, 1992). Advocates of the large-scale approach also assume support staff will provide considerable help to facilitate such change and that they will be available on an "as-needed" basis to work with integrated students.

In comparison with the case-by-case alternative, large-scale integration is more efficient, say proponents. For example, it presumably circumvents the time-consuming and costly process of testing, labeling, placing, and reevaluating. More important, with everyone in regular education, the need for and high cost of a second, partly duplicative, special education system — separate teachers, administrators, credentialling process, programs, and budgets — is eliminated (see Wang, Reynolds, & Walberg, 1988). Moreover, say the advocates, large-scale mainstreaming will force regular education to reform itself because it no longer will have the proverbial "dumping ground" of special education to which it once sent students it deemed "unteachable" (see Fuchs, D., & Fuchs, L. S., 1994, for discussion of this point).

We Choose Case-by-Case, But . . .

Despite these purported benefits, we adhere to the traditional case-by-case approach — not for the sake of tradition, but because its individualized approach to integration increases the likelihood that students' unique needs will be addressed, that they and their parents will have a choice of placements, and that teachers and parents of students with disabilities will not be required to engage in the high-stakes gamble that regular education will indeed accomplish the revolutionary reforms it must for large-scale mainstreaming to work. Moreover, there currently is a very small body of research on the efficacy of large-scale mainstreaming; we do not have the technical know-how to implement it and expect success. In fairness, however, the same can be stated about our preferred alternative, case-by-case reintegration.

Where's the research? Few studies of the case-by-case strategy exist. In a recent review of eight special education journals for 16 years and of the ERIC computer data base, Scott and D. Fuchs (in preparation) found only nine investigations that attempted to validate an explicit process for moving students from a more restrictive to less restrictive setting. Many educational researchers and policymakers do not recognize that reintegration has been understudied because such investigations are often equated incorrectly with the more numerous mainstreaming studies. Mainstreaming studies, by definition, explore the effects on students with disabilities of *being there;* the students have already re-entered before such studies start. Reintegration studies, by contrast, focus on the process of *getting there:* They begin with the student participants in special education, not regular education, settings. Thus, we know precious little about how effectively to move students with disabilities from special education to regular education, irrespective of our preference for case-by-case or large-scale. All of which leads to the Peabody Reintegration Project.

Peabody Reintegration Project. For several years we and our colleagues at Vanderbilt University, in collaboration with local educators, have been trying to develop an effective, efficient, and responsible process for transferring students with learning and behavior problems from various special education settings (especially resource rooms) to less restrictive settings (mostly regular classrooms). As part of this work, which is known as the Peabody Reintegration Project, we have conducted a series of quasi-experimental studies, several of which have been published in scholarly journals (e.g., D. Fuchs, L. S. Fuchs, & Fernstrom, 1992; D. Fuchs, L. S. Fuchs, & Fernstrom, 1993; D. Fuchs, L. S. Fuchs, Fernstrom, & Hohn, 1991). Together with our unpublished studies, these have involved scores of schools and more than 100 teachers and students with disabilities in several contiguous districts in Middle Tennessee. Research findings indicate that our methods help special educators prepare their students for reintegration into mainstream math and reading classrooms. The following sections outline our research results in somewhat more detail after an initial description of the interventions and the process by which teachers participating in the Peabody Reintegration Project work to achieve successful integration for some of their students in the area of reading.

BASIC CONSIDERATIONS: CURRICULUM-BASED MEASUREMENT AND TRANSENVIRONMENTAL PROGRAMMING

Curriculum-Based Measurement (CBM)

CBM is a set of standardized procedures for obtaining reliable and valid measures of student achievement, which in turn facilitate teachers' formative evaluation of their teaching effectiveness. CBM procedures have been developed for measuring progress in reading, spelling, written expression, and math and represent an alternative to commercially distributed achievement tests (see Deno, 1985). Research demonstrates that instructional programs designed with CBM can result in greater student achievement, improved teacher decision making, and enhanced student awareness of their own performance (L. S. Fuchs, Deno, & Mirkin, 1984; L. S. Fuchs & D. Fuchs, 1986).

CBM and reintegration. There are two reasons for special and regular educators to use CBM in reading instruction. First, it permits them to conduct frequent assessments of academic progress, with which they may judge readiness for and adaptation to mainstream reading on a student-by-student basis. Second, CBM data are used by special and regular educators to develop more effective instructional interventions.

CBM reading "maze" assessment. Special educators determine an appropriate reading level on which to establish each reintegration candidate's year-end goal, that is, the level of reading material that the teacher hopes the student will master by April or May of the current year. Teachers assess the reintegration candidate's reading performance two or three times weekly, each time on a different passage, a random sample from the goal-level pool of passages. These reading assessments are administered and scored automatically by computers. Students are permitted 2.5 minutes to complete a maze (i.e., cloze procedure) of a 400-word passage displayed on a computer screen. The first sentence is presented intact; thereafter, every seventh word is deleted and replaced with three choices. Only one is semantically correct. The student must use the space bar and <RETURN> key. Performance is scored as the number of correct replacements. (For more description, see L. S. Fuchs, D. Fuchs, Hamlett, & Ferguson, 1992). Reliability and validity of this computerized assessment may be found in Espin, Deno, Maruyama, and Cohen (1989), L. S. Fuchs and D. Fuchs (1990), and Jenkins and Jewell (1992).

Transenvironmental Programming (TP)

TP (e.g., Anderson-Inman, 1986) is a process to reintegrate pupils into mainstream settings. Although it has been the focus of several single-subject reintegration studies (e.g., Anderson-Inman, 1981; Anderson-Inman, Walker, & Purcell, 1984), we are unaware of prior, larger-scale efforts (excepting our own) to explore its effectiveness or to study it in combination with CBM use. TP comprises four phases, the first of which is *environmental assessment*. Because it is assumed that effective preparation of a student with disabilities for mainstreaming can be accomplished best by first identifying the academic and behavioral expectations of this environment, the purpose of the first phase is to ascertain the specific skills and behaviors required for success in the regular classroom. This knowledge then can be used to help plan the content of instruction in the special education setting.

In the second phase, *intervention and preparation*, the special educator teaches the skills identified during the preceding phase. Next, in *promoting transfer across settings*, the special education teacher helps ensure that the reintegrating student actually uses the newly acquired skills in regular education. In the final phase, *evaluation in the mainstream*, data are collected on the extent to which the student has adjusted academically and socially.

BEST PRACTICES

In the following description, participants are the special and regular educators; the student targeted for reintegration, hereafter referred to as the "reintegration candidate"; and project staff. This last group consists of Peabody/Vanderbilt graduate students trained to provide technical assistance to facilitate the successful completion of project activity. Because it is football season as we write this chapter, and because the first author is a devotee and aficionado (his preferred terms for "fanatic"), you will notice and hopefully forgive allusions to that sport.

Step #1: Recruiting the Players

The special educator is responsible for selecting one or more students who could be ready to reintegrate into a regular class for reading instruction at some point during the school year. That is, the student need not be ready for mainstreaming right away, but maybe in 2 to 4 months, following work in reading or efforts to improve his or her school behavior or social skills. Choosing a student for possible reintegration does not commit the student (or the special educator) to reintegration. If, after some time, the teacher believes insufficient progress has been made, he or she can decide against mainstreaming. The decision to mainstream, then, is ultimately a teacher decision, or teacher-parent decision, or teacher-parent-student decision. To facilitate the selection of appropriate reintegration candidates, we give special educators two "true story profiles" of successfully reintegrated students. ("True Story Profiles" are available from the first author.)

For each selected reintegration candidate, the special educator also identifies a mainstream reading teacher. If two or more such teachers are available for a given student, the special educator chooses the one most likely to be receptive to mainstreaming. The special educator is reminded that this teacher need not be a "perfect" teacher or his or her best friend. Instead, the regular educator should be open-minded and willing to accept responsibilities associated with project involvement.

This teacher is invited to a meeting with project staff and the special education teacher, who communicates the project's purpose, describes the reintegration process, and specifies the roles and obligations of each participant. The special educator provides evidence that the reintegration candidate is currently, or soon will be, ready for return to a mainstream reading class. Such evidence includes the student's level of reading performance and a description of his or her classroom behavior. To facilitate this communication, the special educator shares a "profile" form on the student completed prior to the meeting. (A "Reintegration Student Profile" form may be obtained from the first author.) As reflected by the items on this form, the special educator is encouraged to present a balanced view of the candidate, documenting both strengths and weaknesses. The regular educator is then asked whether reintegrating the student during the current school year seems feasible. After the teacher's (generally positive) response, the special educator makes clear that such a solicited judgment is not binding and that reintegration need not be immediate.

Step #2: Identifying the Competition

During this same first meeting, project staff states that successful reintegration often requires knowledge about both the student and the general education classroom. The staff person indicates that a frequently useful question about the regular classroom is, "What's the lowest acceptable level of academic performance?" In this vein, the mainstream teacher is asked to think of two current students who, although low achievers, are not in jeopardy of referral for possible special education placement. These students will become the standard or, in a sense, the "competition" against which the reintegration candidate's academic progress will be compared. Hereafter, they are referred to as "lowest achieving peers," or "LAPs."

Step #3: Scouting with a Classroom Inventory

The special and general educators and project staff meet a second time to (a) discuss the reintegration candidate's legitimacy and the general educator's willingness to participate in the reintegration process, (b) share information about the candidate and their respective instructional settings, and (c) identify aspects of the student's performance and the two classrooms that require modification to enhance the likelihood of the student's successful transfer to the mainstream setting. Toward these ends, each teacher completes a three-part Classroom Inventory during their second meeting. (A complete copy of the "Classroom Inventory" may be obtained from the first author.)

Part 1. Part 1 of the inventory is meant to provide a snapshot of a classroom's instructional environment, for reasons explained later. It uses a combined checklist and Likert-type format and addresses a potpourri of instructional issues, such as permissible student behavior (e.g., how much movement and talking is allowed); expected student performance (e.g., how often students are required to respond orally); the ways a student gets directions about in-class and out-of-class assignments and help from the teacher when experiencing difficulty; and so forth.

Part 2. Contrastingly, Part 2 makes use of open-ended items and asks many more questions that, in aggregate, explore in depth how instruction gets delivered. Questions in Part 2 concern allocating time for reading; grouping students for instruction; naming primary and supplementary reading texts; presenting new skills and vocabulary; assigning independent in-class work and homework; determining student grades; doling out rewards and punishment; modifying instruction when students do not understand; and so forth. This second part of the inventory makes use of a double-column response format; both special and regular educators answer the same question so that their answers appear side by side. Responding to the same questions in each other's company, and recording answers side by side, is expected to increase teachers' awareness of the similarities and differences between their respective instructional settings and the possible implications of these between-setting differences for the reintegration candidate.

Part 3. Part 3, also completed during the second meeting, taps teachers' expectations for performance and classroom deportment. Reflecting the influence of Walker and Rankin's (1983) SBS, this part of the inventory makes use of a rating scale (where 1 = "critically important," 2 = "desirable but not critical," and 3 = "unimportant"). Teachers use it to communicate the relative salience of various student characteristics and actions. For example, teachers rate the importance of assuming responsibility for materials, listening and complying with directions, using appropriate means to seek teacher attention, ignoring distractions, cooperating with peers, and so on.

CBM training and classroom observations. Completion of the inventory generates rich descriptions of the reintegration candidate's current and (presumably) future classrooms. Completion also triggers two important activities that must be undertaken prior to a third meeting between the two teachers and project staff. First, the reintegration candidate and LAPs are trained to take CBM probes in reading at the computer, and they begin these once (LAPs) or twice (reintegration candidate) weekly. Second, using Part 1 of the inventory as a guide, the special educator observes the mainstream teacher's reading class. Project staff encourages the mainstream teacher to reciprocate if his or her schedule permits. This observing in one another's class familiarizes both teachers with the reintegration candidate's current and future settings and helps the teachers identify discontinuities across instructional environments.

Step #4: The Game Plan

A third meeting of teachers and project staff has four objectives: (a) to assess the progress and validate the choice of the reintegration candidate; (b) to identify salient discrepancies between the two classrooms and between the reintegration candidate's performance/behavior and the mainstream teacher's expectations; (c) to select interventions addressing the discrepancies, which would be implemented in special education and/or the mainstream reading classroom; and (d) to secure the participation of all parties for the duration of the project. The first objective (assessing the progress and validating the legitimacy of the student as a reintegration candidate) is addressed by reviewing the student's CBM performance since the last meeting and comparing it to that of the LAPs. If the student's progress is judged less than satisfactory, this is a last opportunity for the special educator to recommend an alternate child. On the other hand, if the student's performance is as strong as or superior to that of the LAPs, the teachers may decide to transfer him or her at once to a regular classroom. In this case, the teachers would schedule an IEP meeting and discuss instructional interventions and CBM monitoring in the mainstream.

Addressing discrepancies between settings. If the teachers agree on the appropriateness of the candidate — that he or she might require additional time and work in special education, but eventual mainstreaming is likely — the two review their completed inventories and discuss their observations in one another's class to determine whether, and if so which, features of the classes are different. Furthermore, they try to ascertain whether these differences represent potential problems for the reintegration candidate. If salient differences are found, one or more becomes the focus of change. Let us say the special educator observed the mainstream teacher to monitor and praise student work infrequently. By contrast, the regular educator noted the special educator to monitor and praise student work with regularity. Responding to these disparities, the two might decide that the special educator should encourage the reintegration candidate to work more independently and with less encouragement. In so doing, they would be attempting to align special education instruction more closely with mainstream instruction and, presumably, facilitate a smoother student transition.

Addressing discrepancies between teacher expectations and student performance: Impact Strategies. A similar process is followed when exploring possible discrepancies between the reintegration candidate's performance/behavior and the mainstream teacher's expectations. It is often the case that both teachers express concern about the reintegration candidate's reading performance. For this reason, project staff gives teachers a set of "Impact Strategies" — techniques based on the research literatures in reading and special education instruction that address fluency and comprehension development (see Figure 2). Each strategy is described on one or two typed pages, which offer a rationale and directions for implementation. Oral Preview, Silent Review, and Repeated Reading strategies address fluency; Sequencing, Main Idea, Story Mapping, and Content Webbing are the comprehension activities. In addition to a rationale for and description of these strategies, staff also provides practice materials. However, staff does not require teachers to use these strategies and materials; teachers are encouraged to generate their own.

Discrepancy Plan Sheets. To help the teachers conceptualize their "game plan," and to provide a means of recording who would be doing what to whom, they also receive Discrepancy Plan Sheets (see Figure 3). These encourage formulation of an explicit "plan of action," "expected outcomes," and "maintenance" activities in the mainstream classroom. The Discrepancy Plan Sheets represent something of a contract between the teachers, whereby the special educator pledges to implement strategies and setting modifications to prepare the student for reintegration and the regular educator agrees to various modifications to make the mainstream more hospitable once the student transfers.

Step #5: Executing the Game Plan in Special Education

In a word, the purpose of this step is "preparation." The special educator is expected to use the Impact Strategies, or some other instructional strategies, with the reintegration candidate to promote reading growth, which, as mentioned, is indexed by twice-weekly CBM probes. If such feedback indicates insufficient progress relative to the LAPs' growth, the special educator is expected to modify the instructional approach. The student, meanwhile, tries to best previous performance on the probes. If necessary, the teacher and student work together to modify the student's classroom behavior, bringing it into closer conformity with the future teacher's expectations. The

FIGURE 2. Impact Strategies.

FLUENCY

The fluency packets provide the student with repeated exposure to text which should increase automaticity of word recognition skills, enabling the student to focus on the meaning of text rather than reading the words correctly. Oral Preview is designed for a very dysfluent reader who needs to hear a model of fluent reading. Silent preview and repeated reading are designed for more fluent readers. All three processes are designed to enhance the student's ability to read the passage smoothly, with few mistakes, and to increase comprehension.

Oral Preview

Provides students repeated practice on text by allowing the student to hear a model of fluent reading before reading orally.

Silent Preview

Provides students repeated practice on text by allowing the student practice reading text silently before reading orally.

Repeated Reading

Provides students repeated practice on text by allowing the student practice reading with a fluent model before reading a passage independently.

COMPREHENSION

The comprehension packets are arranged in a hierarchy of difficulty. Students should master sequencing before proceeding to the main idea and so on. The end goal in the comprehension series is for students to master the Story Mapping packet for fictional text and Content Webbing for nonfiction.

Sequencing

Has been identified as a critical skill for comprehending text and as a prerequisite skill for more complex comprehension strategies such as story mapping.

Main Idea

Provides practice with identifying the main idea of a passage, which is a critical skill for comprehending text.

Story Mapping

Enables a student to identify the major structural features of a story, thereby strengthening his or her understanding of the text.

Content Webbing

Assists students in organizing content area text and can result in increased comprehension. It incorporates a number of reading and reasoning skills such as identifying the main idea and supporting details and classifying and organizing information.

"game plan," then, has a relatively narrow focus. It is based on the salient discrepancies identified jointly by special and regular educators; the plan is not to "fix" the whole child, nor to make him or her perfect prior to mainstreaming. Across several years, special educators participating in the reintegration project take, on average, 2 to 3 months to help prepare their students for transition.

Step #6: On the Road

Transition from special education to regular education is coordinated with a fourth meeting at which it is determined whether the reintegration candidate has achieved sufficient progress to warrant either full-time or gradual inclusion in the regular reading classroom. If the decision is affirmative for one or the other, the teachers (a) review the mainstream teacher's planned accommodations for the new student, (b) discuss what supports, if any, are required, and (c) plan for follow-up communication. If this transition requires a change in the student's special education status, project staff propose that a multidisciplinary team meeting be held. Whether such a meeting occurs is left to the discretion of the teachers. If the teachers decide against reintegration at this time, they review both their goals and intervention strategies for the student.

Step #7: Executing the Game Plan in the Mainstream

The regular educator's adherence to the game plan, developed during Step #4 and revisited in Step

#6, is monitored by either project staff or the special educator once or twice each week for about 8 weeks. Staff also helps the mainstream teacher to ensure that the reintegrated student and LAPs continue on a weekly basis to take their CBM probes. About 8 weeks after the student's transition, the teachers meet for a fifth time to evaluate his or her progress in the regular classroom. This meeting occasionally represents an IEP meeting, to which the student's parents and others, sometimes the student, are invited to deliberate about changing the student's special education status.

EVALUATING CASE-BY-CASE MAINSTREAMING

Building Half a Bridge

For several years, we have implemented and evaluated experimental procedures for reintegrating students in reading and math mainstream classes, always searching for effectiveness and efficiency. Findings from this research and development program have been both encouraging and disappointing. During the 1988–89 school year, for example, we assigned 42 students with mild disabilities to experimental and control groups. We assisted special and regular educators in the experimental condition to implement CBM and TP to prepare selected students for reintegration into mainstream math classrooms. Math progress was measured by pre- versus posttreatment and ongoing curriculum-based achievement data obtained in special and regular education settings and by teacher reports. Findings indicated that experimental students substantially reduced time spent in special education math, whereas control students' time in special education math was unchanged. Experimental students' pre-to-posttreatment achievement was greater than that of controls and was similar to the progress of lowest-achieving nondisabled students in mainstream classes. Time-series analysis revealed, however, that experimental students' improved performance occurred only in special education; once in the mainstream, their progress ceased (see D. Fuchs, L. S. Fuchs, & Fernstrom, 1992; D. Fuchs, L. S. Fuchs, & Fernstrom, 1993).

These findings were replicated in reading in 1992–93 in the same school districts. On the computerized reading assessment (described previously), 11 reintegration candidates registered an average gain of 3.71 maze restorations, or words chosen correctly to complete a passage, in approximately 2.5 months in special education. Control students' math gain was only 1.25 maze restorations. In contrast to their progress in special education, the experimental students' average gain in regular reading classes during an equal interval of time was a mere .27 maze restorations.

How might we explain the experimental students' disappointing performance in mainstream reading and math classrooms? Anecdotal evidence suggests at least two reasons: First, in the districts in which we were operating, special and general educators have little time to talk with each other. Once reintegration candidates were mainstreamed, very high pupil–teacher ratios in special education and an absence of structured consultation time militated against a continuing dialogue about the student with disabilities. Second, regular educators may think individualized instruction is valuable in principle, or when someone else is doing it, but, like the proverbial domestic who draws the line when it comes to windows, general educators with whom we have worked typically "don't do individualized instruction." It is something for which they were not trained and for which they have little patience (see Baker & Zigmond, 1990; Zigmond & Baker, 1993). Thus, once the reintegration student transferred to the mainstream, she or he failed to obtain the tailor-made accommodations in instruction, curriculum, behavior management, and so forth provided through CBM and TP in special education.

Irrespective of why, our reintegrated students' inadequate performance in the mainstream prompts this question: How long will they be tolerated before their academic progress or behavior is (once again) viewed as too discrepant from class norms to justify their continued presence? A follow-up study we conducted provides a sobering answer. During the 1989–90 academic year, 32 students who had experienced TP or CBM or both in special education were transferred full time to regular education math classrooms. One year later, only 56% of these children were still in the mainstream; 44% were once again receiving their math instruction in special education.

Thus, we and our school-based colleagues have succeeded in building half a bridge: We have demonstrated that by the use of CBM and TP, special educators can boost selected students' achievement levels in reading and math to a point recognized by all parties as commensurate with mainstream expectations. The rub comes following reintegration when the students' reading and math progress stops. To build the second half of the bridge, we have turned to classwide peer tutoring.

Classwide Peer Tutoring (CWPT)

CWPT was first developed at the Juniper Gardens Children's Project in the early 1980s as a technique for improving children's learning in urban schools (e.g., Delquadri, Greenwood, Stretton, & Hall, 1983). It was found to increase students' opportunities to practice reading and to permit teachers greater flexibility in the use of reading texts (Greenwood, Carta, & Kamps, 1990). Reading procedures focused on developing students' fluency by requiring them to read connected text while being supervised by a peer. During the past 5 years, we and our colleagues at Peabody/Vanderbilt have attempted to extend the Juniper Gardens' model. The Peabody CWPT version (D. Fuchs, Mathes, & L. S. Fuchs, 1993) includes three reading activities: Partner Reading, Paragraph Shrinking, and Prediction Relay. The focus is on enhancing comprehension by directing students to engage in processing strategies designed to help them understand and remember text and monitor their comprehension. These strategies include (a) cumulatively reviewing information read, (b) sequencing information, (c) summarizing paragraphs and pages, (d) stating main ideas in as few words as possible, and (e) predicting and checking outcomes.

In Peabody CWPT all students in a teacher's class are paired. Each pair includes a higher and lower performing student. The roles of tutor and reader are reciprocal; that is, each student in a pair serves as reader for part of the time and as tutor for an equal portion of time. The higher performing reader reads first for each activity and serves as a model for the lower performing reader. Pairs are assigned to one of two teams for which they earn points. Points are awarded for engaging in reading activities and for behaving appropriately during tutoring. At the end of an instructional week, points are reported to the teacher; total points for each team are determined; and the winning team is announced. After 4 weeks, new pair and team assignments are made so that no team is consistently better or worse. Paris are always assigned to the same team. Thus, the motivational procedures combine competitive and cooperative features. Research indicates that Peabody CWPT promotes markedly better reading achievement than does conventional instruction in a wide range of learner types, including those with learning disabilities and low-achieving and average-achieving students (D. Fuchs, L. S. Fuchs, & Mathes, 1993).

Our hope is that CWPT will help make the mainstream somewhat more responsive and hospitable to the reintegration student and provide some of the individualization of instruction and nurturance necessary for the returning student's continued academic growth. This academic year, we are exploring experimentally the "value added" of CWPT by comparing a CBM + TP + CWPT condition to a CBM + TP condition to controls.

Serious problems are associated with developing an effective case-by-case approach to reintegration. No doubt about it. But so, too, are there many unanswered questions connected to large-scale mainstreaming. Because case-by-case reintegration embodies the individualization principle and exemplifies what's special about special education, and because case-by-case reintegration is supported by federal law, we hold that it is the more responsible way to try to move children into more integrated settings.

SUMMARY

Few special education teachers, administrators, teacher-trainers, or researchers are satisfied with the low frequency with which students with disabilities are transitioned into less restrictive educational settings. For these professionals the question is not whether many of these children should be prepared for reintegration, but how to do it in a responsible manner. During the last decade, cooperative learning models have been developed that aim to mainstream — all at once — large numbers of special-needs students. This chapter describes an alternate strategy: case-by-case reintegration that combines CBM and TP. It was developed to facilitate the successful transition of students with mild and moderate disabilities into regular reading and math classes. By "successful" we mean reintegrating students in such a manner that (a) they have the skills and behaviors required by the mainstream setting prior to entry, and (b) the regular educators are familiar with their strengths and weaknesses and confident that they are prepared to perform adequately and behave appropriately. In several years of research, we have shown that by use of CBM and TP, special educators can boost students' achievement levels to a point recognized by all parties as commensurate with mainstream expectations. However, we also have found that, once in the regular classroom, these students' academic progress typically ceases. Thus, we, and the teachers with whom we have been working, have succeeded in building half a bridge. To complete it, we have turned to CWPT with the expectation that it will help make mainstream instruction more responsive and hospitable to the reintegrating student.

AUTHORS' NOTE

Preparation of this chapter was supported in part by the Office of Special Education Programs in the U.S. Department of Education (Grant No. H023C10086-93) and by the National Institute of Child Health and Human Development (Core Grant HD15052). The chapter does not necessarily reflect the position or policy of the funding agencies, and no official endorsement by them should be inferred.

We thank the special and regular education teachers who have worked with us on our reintegration project, and Sue Dutka, Jill Howard, Wendy Locke, Patricia Mathes, and Marcia Stewart, whose help has been invaluable during project implementation.

Inquiries should be addressed to Douglas Fuchs, Department of Special Education, Box 328, George Peabody College, Vanderbilt University, Nashville, TN 37203.

Best Practices in Individual Counseling of Elementary-Age Students

Deborah Tharinger
Mary Stafford
The University of Texas at Austin

This chapter provides a theoretically integrated and pragmatically oriented framework for the provision of school-based individual counseling to children by school psychologists. Other important intervention services that can be provided by school psychologists — such as group counseling, crisis counseling, family counseling, milieu counseling (e.g., in school-based day treatment programs), and teacher support programs, although they are necessary to an integrated approach and the concept of a continuum of care of school-based health and mental health services — are not addressed here. The chapter is addressed to school psychologists who desire to engage in direct and coordinated interventions with children to promote their development and learning by helping to alleviate their distress and behavioral dysfunction.

When addressing "best practices" in counseling children, it is important to recognize that school psychologists come from varied training and practice traditions, function in uniquely defined roles within different school districts, practice in distinct ways within the same roles (e.g., counseling children), and have different views of the future practice of school psychology. Although the practice of school psychology in most schools continues to be dominated by an assessment role, a counseling role often is available. This role for the school psychologist can be limited to counseling that is provided exclusively to children designated as seriously emotionally disturbed in the special education system or can be as extensive as including all children in need, services being prioritized through a screening and referral system. In addition, a school psychologist may be the only provider of mental health services in his or her school site, or may work collaboratively with school counselors, social workers, nurses, and prevention specialists. Furthermore, one school psychologist may have adopted a model of child counseling with extensive parent and teacher involvement, while another may focus primarily or exclusively on the child. These many differences among school psychologists reflect philosophical, theoretical, and pragmatic influences that impact on attitudes and the sense of "best practices" of counseling in the field.

In this chapter, the position is taken that for school psychologists who counsel children individually in the schools there is not a single best practice that can be specified in terms of a particular theoretical framework or implementation method. However, there is a best practice in terms of functioning from a theoretically, ethically, scientifically, and humanly driven orientation that maximizes competent and effective service delivery. Thus, what is presented in this chapter is best viewed as *one* such integration that offers guidelines to those who are currently counseling children or who aspire to do so. It is acknowledged that the perspective and integration proposed will appeal to some, but certainly not all, practitioners and trainers. In particular, in light of the problem-solving approach being stressed throughout this volume, a problem-solving orientation is central to this chapter in the sense that the counseling process involves constant hypothesis testing and adjustment. However, any use of a formal problem-solving approach or curriculum is seen as one of the many possible therapeutic techniques that can be employed in the context of the counseling relationship. Counseling with children as presented in this chapter is informed but not limited or unduly determined by a problem-solving approach.

This chapter is influenced by the view that school psychologists can be primary providers of mental health services for children (and their teachers and caretakers) within the health provision system of the schools. A child–school–family philosophy is stressed that involves home and school caregivers, in addition to the child, in the counseling process. Theoretically, the chapter is guided by an integrated model of counseling that emphasizes a developmentally and culturally sensitive relationship approach, influenced by attachment theory and buttressed by recent innovations in cognitive behavioral and systems/ecological theory. Central to this view is the perception that the counseling relationship provides the child with a secure base from which to explore her or his relational, physical, cognitive, and internal world and from which to choose to make or respond to changes. The relationships the school psychologist establishes with the child's caregivers and teachers also can provide them with a secure base from which to explore their attitudes, influences, and reactions to the child, as well as their motivation to engage in and support change for the child and themselves. In this model, the child is seen as the primary client, with secondary relationships established with parents and teachers.

The remainder of this chapter is divided into three parts. The first, an overview, examines children's unmet mental health needs, the uniquenesses and challenges involved in counseling children in the schools, considerations in selecting children for counseling, the process and general goals of counseling, and characteristics conducive to being a counselor to children. The second section addresses basic considerations, with a focus on developmental and cultural influences, and discusses the essential knowledge necessary for counseling children. The final section provides a seven-stage model designed to guide school psychologists in constructing their own best practices in counseling elementary-age children.

OVERVIEW

It has been acknowledged widely that there has been a failure to respond to the mental health needs of the vast majority of children in all settings, including the schools. This point has been brought home strongly in the past decade by Jane Knitzer in her 1982 book, *Unclaimed Children: The Failure of Public Responsibility to Children and Adolescents in Need of Mental Health Services*, and in her more recent book (1990) written with colleagues Steinberg and Fleisch, *At the Schoolhouse Door: An Examination of Programs and Policies for Children with Behavioral and Emotional Problems.* It is estimated that at least 12% of children and adolescents suffer from emotional and behavioral disorders and at least 5% are thought to suffer from serious emotional and behavioral problems. Furthermore, it is estimated that at least 70%–80% of these children are not receiving necessary mental health services, and that the children from minority groups are the most underserved (Tuma, 1989). The large majority (80%) of children and adolescents with serious emotional disturbances and mental health needs attend the public schools (Knitzer et al., 1990). Currently the schools are being viewed as a key setting for the delivery of many of the mental health services, both intervention and prevention, that children may need (Holtzman, 1992), and school psychologists can be central providers. It is useful to review many of the unique and challenging aspects of delivering mental health services to children in the schools.

Unique and Challenging Aspects of School-Based Counseling with Children

There are unique and challenging aspects to how children, the environment of the school, and a collaborative framework affect the counseling process. It is important to examine these influencing factors, as they impact on the effectiveness of counseling and the receptivity of the system to counseling services. Clarizio and McCoy (1983) have described unique aspects of counseling children and conclude: (a) that children are unlikely to seek help voluntarily or to initiate entry into counseling; (b) that most children lack an explicit understanding of counseling, the purpose and goals of treatment, and the role they are to assume; (c) that children's verbal and cognitive abilities, as well as the organization of their personalities are in development; and (d) that children are extremely dependent on and influenced by their immediate environments, most specifically their families and their schooling experience. Although these characteristics of children may appear to be limitations, they also can be viewed as opportunities for practitioners to educate the adults in children's lives as well as the children about the potential benefits of counseling, to work with children early in their personality development, and to influence the significant others in children's lives while they are still energized, motivated, and committed.

One major advantage to counseling children within the school setting is that one is working in the child's world — a natural setting where children come every day. One has access to children's teachers, administrators, and other personnel who interact with the child. In addition, one has the opportunity to experience a complete cohort of children in a particular school, and to get a sense of where and how a particular child does and does not fit in. In other words, there are inherent local norms in the schools for comparison purposes. In addition, involvement and feedback from teachers about the child's progress can be obtained. There also may be the opportunity, depending on the continuum of services available in the school, to provide a child with a combination of individual, group, and family-related services. Moreover, it may be possible to coordinate a variety of services with other professionals in the school, such as a school counselor or social worker. Lastly, there is an opportunity for long-term follow-up, even over several years, to track the development of an individual child and his or her family.

The challenges involved in counseling children in the school include finding a good fit between the goals and process of the educational system and the goals and process of counseling, with its origins in the psychology and mental health arenas. The educational and the mental health systems, although similarly invested in promoting growth in children, have somewhat different perspectives and priorities.

These differences have the potential for raising conflicts among the school psychologist, teachers, administrators, other school personnel, and parents. The primary goal of the schooling perspective is to educate all children, with a focus on academic progress, group socialization, and appropriate behavior. The primary goal from the mental health perspective in the school environment is to assist individuals in solving emotional, behavioral, and interpersonal problems that are impinging upon their being able to take full advantage of academic and socialization experiences. Though the end goals are the same, the means may be quite distinctive. The school psychologist needs to impart to teachers, administrators, and parents that children will profit from the educational environment only if their mental health needs are reasonably met.

Another challenge to a model of school-based counseling that includes consultation with teachers and parents is finding effective ways to involve them. Teachers usually will cooperate in order to alleviate the child's emotional and/or behavioral distress in the classroom, and they often are more than willing to collaborate on classroom interventions in conjunction with individual counseling. However, the teacher's available time for consultation may be minimal and proposed solutions must consider the target child's needs in relation to the needs of the rest of the children in the classroom. In addition, the teacher's role and responsibilities are influenced by the direction the school's leadership takes, affecting what type of changes are acceptable in the child's classroom. Involvement of parents in a child's counseling allows for the formation of a partnership between the family and school that may not have existed previously (Christenson & Conoley, 1992). Many parents want to be involved in the process of deciding their children's educational programs and involvement in counseling. However, the factors that interfere with the school psychologist's efforts to facilitate the development of partnerships between families and schools include (a) work schedules that limit parents' availability to meet during the day, and childcare responsibilities that interfere with their availability during the evening; (b) some parents' belief that schools should handle school matters, including managing the child's school behavior and discipline, rather than asking parents to intervene; (c) resistant communication because parents often receive only negative feedback from the school about their child; and (d) some parents' belief that their children should spend school time in academic activities rather than in other activities, including counseling. While beliefs often are hard to change, there are some things that schools and school psychologists can do to increase parents' involvement and to facilitate partnerships. It is important for school personnel to provide an atmosphere that is family-friendly and scheduled so that families can more easily be involved. Providing childcare for younger siblings during meetings, scheduling meetings at late or very early hours, overtly recognizing the parent as the most knowledgeable person about the child, and structuring a program for the child that includes communication of the child's positive accomplishments and strengths may facilitate the formation of the home–school partnership.

Pragmatic challenges to counseling in the schools consist of managing the many changes and disruptions that happen in the school day and securing private, child-friendly physical space. Counseling in many other settings consists of a clinical hour in a private, quiet office and perhaps a playroom where interruptions are held to a minimum. In these settings, consistency in time and physical location are symbolic of the psychological safety and security being offered to the child. In contrast, space is at a premium in many of today's schools, and schedules are affected by school-wide standardized testing, field trips, assemblies, classroom tests, and detention, as well as meetings and crises that are imposed upon the school psychologist. Efforts must be made to secure and maintain a physical environment and schedule where respect can be shown to both the child and to the counseling process. For example, educating others not to interrupt a session by knocking on the door and having a phone with a silent ring that takes messages can control many of the intrusions to the process. For counseling children individually, the office space does not need to be large, but it does need to be equipped in a way that welcomes children and promotes safety and security. It also is important to provide materials and toys that allow for the expression of anger and aggression, as children have few releases for these feelings, especially at school. Recommended materials and toys for working with elementary-age children in counseling include paper, crayons, magic markers, scissors, clay, puppets, dolls, games (of various developmental levels), stuffed animals, building blocks, plastic animals, monsters, and if possible, a doll house and a blow-up "bobo" punching bag. In addition, a collection of books that address childhood stressors, such as divorce and death, are good to have and to use with children and their parents, as are problem-solving curricula, usually based on a cognitive behavioral orientation (Kendall, 1991). Fortunately, counseling materials, games, and curricula are readily available through many publishers' catalogs.

A final challenge to counseling in the school involves maintaining whatever level of confidentiality was offered to the child and his or her parents and teachers. Working in a school is a bit like working in a fishbowl: There can be constant pressure to share one's work with other professionals also working with the child. Although collaboration can be extremely useful, school psychologists in these positions must work very hard to respond respectfully to the interests and needs of others involved while at the same time retaining offered confidentiality and privacy. The school psychologist can function as a role model when it comes to respecting confidentiality in the complex system of the school, particularly as it applies to information obtained from parents.

Children to Consider for Individual School-Based Counseling

Children whose behavioral, cognitive, emotional, and/or interpersonal functioning causes them or others moderate to serious distress and interferes with their development or learning are good candidates for individual counseling. Children's difficulties that may indicate needed counseling can include (but are not limited to) coping with attention deficit–hyperactivity disorder, having learning or language disabilities, experiencing family divorce and disruption, being the victim of child abuse and neglect, witnessing family or community violence, experiencing unrealistic parent or peer expectations, experiencing multiple losses, living with parents affected with psychopathology or drug and alcohol abuse, and being the objects of prejudice or stigma. These difficulties may manifest themselves as depression, suicidal thoughts, anxiety, out-of-control behavior, distorted cognitions and emotions, disorganization, and/or impaired relationships. Children who experience these difficulties chronically may be assessed as seriously emotionally disturbed and may be entitled to associated services, such as counseling as part of their individualized educational plan. However, as only 1%–2% of children are so identified in the schools (Knitzer et al., 1990), there are many more children in need who are not being identified through the special education channels. School psychologists with the necessary education and training are in an excellent position to help identify these children, prioritize their needs, and plan appropriate interventions, which may include individual counseling.

Determining whether a child is best served through *individual* counseling services, rather than or in addition to other psychological services, requires attention to a variety of indicators gleaned from information provided by multiple sources, including the child, teachers, and parents. The school psychologist needs to consider the nature of the child's problem, its severity and acute or chronic state, the level of negative forces relative to positive resources acting upon and available to the child, and the child's level of stability at the present time. For example, inclusion in group counseling requires a higher level of stability in the child than that required for individual counseling. In cases of crisis (such as potential for suicide, current breakup of the family, or similar events) or severe disturbances, the child may not be stable enough initially to tolerate or benefit from group counseling. A decision may be made to provide individual counseling initially, followed by group counseling as the child stabilizes and is able to receive feedback from peers constructively, with teacher and family consultation services provided concurrently to both interventions. The factors that influence decisions regarding the appropriateness of individual counseling (either alone or in conjunction with other interventions) also can affect the counseling process and provide a basis for determining counseling goals.

Counseling Process and General Goals

Individual counseling with children can be described as the process of ongoing, planned interactions between a mental health professional and a child who has sought, or for whom someone else has sought, help for a particular problem or set of problems. The professional agrees to attempt to provide conditions to alleviate the child's distress and to improve the child's psychological functioning by directly facilitating change in the child and by promoting and supporting change in the child's environment, most centrally the school and family systems. Psychological functioning includes the child's cognitions, perceptions, emotions, behavior, and relational capacities. The general goals of counseling can include alleviating the child's emotional and cognitive distress, changing the child's behavior, assisting with self-understanding, helping the child meet current developmental tasks successfully, supporting needed environmental changes, and promoting a more positive fit between the child and the systems in which she or he resides (e.g., school and family).

The goals of counseling are achieved through a combination of interpersonal relationships with the child and significant others in the child's life, and the implementation of therapeutic techniques that allow for expression, self-examination, building new skills, and promoting adaptation. The relationship with the child allows for the establishment of a safe place that builds trust, where the child can explore himself or herself and learn and practice new ways of feeling, thinking, and behaving that are designed to promote healthier adaptations and increased options. The relationships with significant others are designed to promote a new understanding of the child, support for change in the child, and hopefully a commitment to examination and change within the adults themselves. The therapeutic techniques applied usually reflect the theoretical orientation and integration of the practitioner and are drawn from psychodynamic, object relations, attachment, humanistic, behavioral, cognitive-behavioral, and family systems theories. Techniques are chosen to fit the needs of a particular child at a given time and to address the goals of counseling. Modalities for working with children are many and include verbal interactions, such as talking, story telling, and dialogue during play; action play; game playing; work with art materials; and use of books and journals. Social skills and self-management training are examples of additional interventions that can complement the individual counseling process.

Being a Counselor of Children

Practitioners who provide counseling to children in the schools are likely to be very diverse; however, it is beneficial if they are hopeful, enjoy being in children's worlds, can create a sense of security, are nonjudgmental, can be playful, are flexible, can be innovative and creative with space and materials, and are talented at getting access to children's thoughts and feelings. Comfortableness with the modalities of talking, play, games, role playing, art, skill building, and sports activities also is needed. It is important to be able to engage in the art of counseling while at the same time being informed by the science of counseling. In addition, being able to balance the crises that occur in the school that compete with regular counseling sessions is essential. The school-based counselor also has to be able to deal with the pressure to change children's behavior very quickly. This type of pressure usually leads to nothing more than "talking at kids" and trying to "straighten kids out," a job best left to an adult in charge of school discipline matters. And finally, the counselor must be effective with children as well as adults, including parents, teachers, and administrators.

Counselors, through training and supervision, need to develop and refine an array of interpersonal and counseling skills as well as develop a sense of themselves as counselors. The skills needed include demonstrating empathy, regard, respect, and caring for other persons, as well as listening, reflecting, confronting, and interpreting — all skills originally described by the humanistic tradition. In addition, informal and formal assessment skills, interviewing skills, consultation skills, capacity to effectively and empathically provide feedback, and limit-setting abilities need to be mastered. It is essential for counselors to be comfortable with their knowledge and skills, and to know when they are outside their areas of competence. In that case, it is important to refer or to obtain supervision and consultation from professionals with the desired expertise. Knowing when the material in a counseling case with a child may be too close to home in respect to a counselor's own pain or unresolved issues (countertransference) is another time for referral, consultation, and/or supervision. With continuing education, training, experience, and professional and personal integration the developing counselor will function confidently in more and more areas of competence.

Thus, just as counseling with a child is a developmental process, counselors themselves undergo a developmental process from a novice counselor to a more expert one. It may be helpful to consider that counselors also need a secure base from which to develop and maintain their counseling expertise; without it, the ability to offer security to others may be compromised. Unfortunately, tremendous external and internal demands are placed on personnel who attempt to address children's mental health needs in many of today's schools, challenging the counselor's own secure base. It has been recognized that secondary trauma and/or burnout can result if providers do not acknowledge and address the level of stress in their worksites and set boundaries between what is possible and what is not. Thus, school psychologists need to foster health within themselves and their workplace that is then reflected in their relationships with children, families, and teachers.

BASIC CONSIDERATIONS

Besides the set of sustaining characteristics described above, counselors of children need to possess a core body of knowledge in order to develop as effective practitioners. Areas that make up this integration include developmental and cultural considerations, theoretical models for counseling, knowledge of the research and clinical literatures, familiarity with children's play and play therapy, psychopharmacology, and professional ethics.

Developmental and Cultural Perspectives

Counseling with children demands a developmental perspective, regardless of the other theoretical influences that may guide the goals and process of counseling. Also, the cultural features of the child must be attended to if counseling is to be effective with the wide variety of children in schools.

Developmental theory and a developmental perspective. Theory organizes and gives meaning to facts, provides a framework for them, and assigns more importance to some facts than others. In addition, a theory provides a framework for raising questions, guiding observations, and generating new information. Theories are useful to the practitioner because they provide heuristics to guide problem solving. Knowledge of developmental theories and frameworks can prevent tunnel vision among practitioners working with children. A rigid perspective on children's behavior can be avoided if one incorporates multiple theoretical perspectives in an attempt to understand children's behavior within a view of the whole child. For example, combining and integrating Freud's concern with underlying motivations and emotions, Erikson's concern with the mastery of psychosocial crises, Piaget's findings on cognitive capabilities, social learning theory's concern with modeling and observation, Bowlby's focus on the quality of attachment and internalized working models, and Bronfenbrenner's concern with transactions between the child and multiple environmental systems produces a powerful perspective for understanding children's development and the forces that effect such development. A developmental perspective is useful for conceptualizing, choosing, and evaluating specific and appropriate counseling goals for each child (Tharinger & Lambert, 1990). In addition, by understanding normal developmental progressions as well as culture- and gender-designated developmental tasks, the practitioner can match the process of counseling to the child's developmental levels.

Although developmental theories are useful for understanding normative development, what is challenging about children who receive counseling is that they are typically outside of the norm in one or more areas of development. Although an understanding of where they "ought" to be or "where most children their age are" is useful, familiarity with approaches that examine individual differences in the developmental process also is essential. For example, the work in the field of developmental psychopathology has raised questions about the continuity and discontinuity in development and has emphasized how normal development can inform abnormal development and vice versa (Achenbach, 1990; Cicchetti, 1990; Lewis, 1990; Rutter, 1990). Also of keen interest has been the child who appears to overcome extreme odds to function in an adaptive, competent manner (Garmezy, Masten, & Tellegen, 1984). What is apparent from this collected work is the complexity of the developmental process in respect to a course of health or a course of pathology, or a weaving in and out between the two. Notions of a fixed continuity of either health or pathology have been shown to be naive, and it is widely accepted that the majority of individuals who have mental health problems as children do not show problems as adults and that the majority of adults who present with mental health problems did not show difficulties as children (Richters & Weintraub, 1990). This general finding supports the concept of discontinuity of development as well as the malleability of the individual, which in turn supports prevention and intervention efforts. Thus, an awareness of risk and protective factors of underlying mechanisms (Rutter, 1990) can help inform the school psychologist about varied developmental paths, enhancing the understanding of each individual child.

Cultural considerations. Developmental perspectives and environmental impacts can be areas of difference between majority and minority group children that may add complexity to the counseling process. Definitions of normal behavior are culturally determined, and thus differ for various cultural groups. Non-western children may differ in the schedule and expression of certain behaviors considered age- and gender-appropriate for U.S. children (Vargas & Koss-Chioino, 1992). For example, some cultures encourage autonomy at earlier ages than others. In addition, environmental impacts, such as poverty, racism and prejudice, and level of acculturation may serve to increase environmental stresses, cause confusion for minority children, and add complexity to the counseling process. Furthermore, if the counselor's culture is different from the child's, misperception and miscommunication on the part of both the counselor and the child may interfere with the counseling process.

The purpose of counseling usually is to bring the child's thoughts, feelings, or behaviors into the healthy range, as well as to alleviate distress and promote more optimal adaptation. However, definitions of normality, distress, and adaptation differ among cultures. Obtaining information from relevant sources about norms for various cultures (e.g., Sue, 1990; Sue & Sue, 1990; Vargas & Koss-Chioino, 1992), as well as gathering information from the child's parents and community members concerning their expectations for normal behavior provide vital data for the counselor to consider in developing counseling goals.

Poverty, racism, and prejudice often intertwine to create feelings of powerlessness and helplessness for the minority child (Vargas & Koss-Chioino, 1992). When poverty is a part of the child's life, often it is accompanied by inadequate housing, nutrition, and consequent poor health. Racism and prejudice often are subtle and may not be overtly recognized by the person delivering or receiving the negative messages. However, even the most subtle statements and actions may be felt severely by the targeted child. Sensitivity to the meaning of statements and actions is likely to result from repeated experiences with even the most subtle forms of racism, resulting in an inability to trust others, especially members of the group delivering the message. When the counselor is a member of a cultural group with whom the child has had negative experiences, interference in the development of the counseling relationship may result for both the counselor and the child. Additionally, the minority child's development of a sense of identity is more complex than that of children from the majority group (Vargas & Koss-Chioino, 1992). Finding one's sense of self in a society where advantages are enjoyed at a greater rate by the majority group is complex and difficult. The counseling process may need to address both the problem areas that interfere with the child's fitting in and the development of a healthy identity within the child's own cultural group.

Levels of acculturation also impact the minority child. First-generation children, who were born of parents in another country have learned behaviors that were considered appropriate in that country. As with all children, their experiences in the early years of their life influence the way they view the world and interpret situations. These children literally are caught between two cultures (Vargas & Koss-Chioino, 1992). It is essential when working with these children, as well as second-or third-generation minority children, to assess strengths of the child and family and culturally specific responses to mental health problems (Lee, 1988).

Counseling children from minority cultures requires an understanding of the child's culture (e.g., value systems, family structure, socialization patterns, verbal and nonverbal language systems), as well as the impact on present functioning of the child's level of acculturation and language proficiency in both the native language and English. Sensitivity to the effect of the counselor's culture on the child and her or his family, as well as the effect of the child's culture on the counselor is necessary for effective counseling. Inclusion of spirituality and other cultural aspects in the counseling process and use of ethnically relevant toys and materials reflects this sensitivity. Models for understanding culturally responsive psychotherapies can be found in Sue (1990), Sue and Sue (1990), Sue and Zane (1987), and Vargas and Koss-Chioino (1992).

Knowledge of Theoretical Models for Counseling: The Need for Integration

Counseling and psychotherapy with children have a rich history influenced by multiple sources (Koocher & D'Angelo, 1992). At the present time there are many recent books (within the past 5 years) on the topic, from a variety of theoretical perspectives, that address general practice as well as counseling and psychotherapy with children with specific disorders or needs (e.g., see Allan, 1988; Barkley, 1990; D'Amato & Rothlisberg, 1992; Dennison, 1989; Dennison & Glassman, 1987; Hodges, 1991; James, 1989; Kazdin, 1988; Keat, 1990; Kendall, 1991; Kernberg & Chazan, 1991; Kratochwill & Morris, 1991; Mordock, 1991; Shirk, 1988; Siegel, 1991; Spiegel, 1989; Stark, 1990; Thompson & Rudolph, 1992; Vargas & Koss-Chioino, 1992; Vernon, 1989; Webb, 1991).

Models adopted to guide counseling usually correspond with the practitioner's explicit or implicit theories of developmental change. Each of the major developmental theories proposes a model of change that can be applied to the counseling process (Tharinger & Lambert, 1990). From the psychodynamic perspective, the goal is to promote emotional and behavior change by interpreting the child's defenses so as to bring unconscious elements that have been impeding development into consciousness. From the psychosocial perspective the goal is to promote resolution of developmentally salient conflict to allow the child an increased sense of mastery, good judgment, and capacity "to do well." From the cognitive developmental perspective the goal is to promote progression to higher stages of cognitive reasoning, thus allowing the child greater cognitive flexibility, a wider range of application of her or his new structural organization, the ability to coordinate more perspectives, and an increased capacity to handle new, unfamiliar problems.

From the social learning and cognitive behavioral perspectives the goal of counseling is to promote behavior change directly by reinforcing desired behavior, by providing positive models and positive vicarious experiences, and by changing children's cognitions — for example, by helping them learn cognitive mediation to control impulsive behavior or by helping them alter negative self-evaluations. From the attachment perspective the goal is to promote interpersonal change by providing a secure base for exploration, by establishing a positive relationship with the children, and by aiding them in understanding the quality of their earlier attachments and the significance of their losses in relation to current behavior. From the ecological and the transactional organism perspectives the goal is to promote behavioral, cognitive, emotional, and interpersonal change by bringing about changes in the children (using the above methods) and in the children's environment. Environment targets include parents (e.g., through parent consultation), family (e.g., through family therapy), teachers (e.g., through teacher consultation), and peers (e.g., through classroom interventions and group counseling). From the developmental psychopathology perspective, the goal of counseling is to facilitate getting the child back on developmental track through addressing the multiple child and environmental transactional factors that may be adversely impacting the child.

Although each of the above models of change is applicable with children and will help promote change if matched with the children's needs and their developmental levels, an integrated perspective provides the most flexible and comprehensive model for change in counseling with children in schools. Arkowitz (1992) provides a useful discussion on integrative theories of therapy, and D'Amato and Rothlisberg (1992) illustrates eight different theoretical perspectives' views on providing psychological intervention for an adolescent. If one accepts that the practitioner cannot effect change optimally by focusing on only one domain of functioning, be it emotional, interpersonal, cognitive, or behavioral, or by ignoring individual difference factors and mechanisms underlying development, then a counselor needs to work simultaneously on cognitive, emotional, and behavioral change, taking into account uniqueness within the individual and his or her environment and culture. In addition, with few exceptions the counselor needs to work with significant adults in the child's world, especially parents and teachers, to carry out change in the child's environment. For an excellent example, see Nathan (1992).

Knowledge of Research and Clinical Literatures

It is also important for school psychologists to be knowledgeable about the clinical and research literature available on treatment guidelines for specific disorders of childhood. There are many reference materials available that specifically address prevalence, specific features, etiology, and treatment guidelines for children who have childhood DSM-III-R mental disorders that frequently lead to a counseling referral, such as attention deficit–hyperactivity disorders, conduct disorders, anxiety disorders, and mood disorders (Barkley, 1990; Hughes, 1988; Kendall, 1991; Kernberg & Chazan, 1991; Kratochwill & Morris, 1991; Stark, 1990). It also is important to have available literature on children's reactions, adjustment, and recovery in relation to such life stressors as loss, abuse, and handicaps. Children dealing with these issues are likely counseling candidates. Fortunately, there is a growing body of research findings on the effects of life events as stressors that negatively affect children's development (Cook & Dworkin, 1992; Johnson, 1986). The literature on the effects of divorce of parents on children's development (Hodges, 1991) and death of parents (Blom, Cheney, & Snoddy, 1986) are important resources offering useful perspectives. As more children experience a portion of their lives in single-parent homes and with stepparents, researchers are investigating the impact of each (Whitehead, 1993). In addition, as professionals have become aware of the high incidence and grave impact of child sexual abuse, conceptual models, research findings, and applications to counseling have been forthcoming (Cicchetti & Carlson, 1989; James, 1989; Tharinger, 1990; Tharinger & Horton, 1992; Webb, 1991).

Knowledge of Children's Play and Play Therapy

Play in a counseling relationship is to the child what verbalization is to the adult (Garbarino et al., 1989). Play is the natural and comfortable medium of expression for children. It is a medium for expressing feelings, exploring relationships, describing experiences, disclosing wishes, and building solutions. Children may not discuss their feelings, but may act them out. Thus, play can be the natural medium for much of counseling or therapy with children. Play therapy does not belong to a particular theoretical orientation. It is a medium, a method of expression and communication. The use of play in therapy has been described from many theoretical perspectives (Kissel, 1990; Schaefer & O'Connor, 1983), including a psychoanalytic perspective (Esan, 1983), a client-centered perspective (Guerney, 1983), a cognitive-behavioral perspective (Meichenbaum, 1977), and a cognitive-developmental perspective (Harter, 1983). The use of play therapy has also been hearalded in work with traumatized children (James, 1989) and children in crises (Webb, 1991).

Erikson (1977) has described play in a broad sense to mean the use of imagination to try out ways of mastering and adapting to the world, to express emotion, to recreate past situations or imagine future situations, and to develop new models of existence. From Erikson's view, problems that cannot be solved in reality can be resolved through doll play, dramatics, sports, art, or playing house. Similarly, Bettelheim (1987) states that to understand children, their play must be understood. Children use play to work through and master quite complex psychological difficulties of the past and the present. From children's play an understanding of how they see and construe the world, what they would like it to be, and a sense of their concerns and problems are gained. Through play, children express what they cannot put into words. Children do not play spontaneously only to pass time: What children choose to play is motivated by their inner processes, desires, problems, and anxieties (Bettelheim, 1987).

It is essential that a counselor working with children respect their need for expression through play. The presence and use of toys and play materials in a counselor's office indicates to children that it is a place for children, that their world is understood there, and that they can be children there. Play materials invite children to participate and establish a natural means of communication that does not require or depend upon verbal interaction. Children's play becomes the medium of exchange and is utilized by the counselor to build a therapeutic relationship, to understand the child, to solve problems, and to practice solutions.

Knowledge of Psychopharmacology

Children are increasingly being treated by practitioners in the medical community with medication, particularly for seizure disorders, attention deficit–hyperactivity disorder, and depression. It is important that practitioners counseling in the schools have a working knowledge of the effects of medication on children, how they can be used as an adjunct to counseling, and how to assist children in helping them understand and be in compliance with medication (for resources, see Barkley, 1990; Dulcan, 1992; Gadow & Pomeroy, 1881; Green, 1991).

Knowledge of Professional Ethics

It is extremely important for school psychologists delivering counseling services in the schools to have and apply a working knowledge of professional ethics. Both the NASP Principles for Professional Ethics (this volume, Appendix I) and the newly revised Ethical Principles of Psychologists and Code of Conduct (APA, 1992) provide guidelines in the areas of competence, integrity, responsibility, and respect and concern for others, which guide general practice. More specific standards on assessment, therapy, privacy, and confidentiality that apply to the practice of counseling also are included in these guidelines.

BEST PRACTICES

A seven-stage model of best practices in school-based individual counseling with elementary students is presented below, giving a step-by-step guide from referral to termination and evaluation of the counseling intervention (see Table 1). To facilitate discussion, the counseling process has been divided into stages; however, boundaries between stages may not be clearly evident in practice.

Stage 1: Assess Appropriateness of Referral for Individual School-Based Counseling

When a referral for school-based counseling is received, an evaluation of the referral needs to be made. A review of both the child's school records and information from the referral source about the reason for referral, presenting problem(s), and steps already taken to alleviate the problem(s) precedes a judgment about the appropriateness of the referral for intervention in general, and individual counseling in particular. Alternative interventions, such as changing the child's classroom assignment or routine, consulting with the child's teachers, creating a behavior management plan, working with the child's family, group counseling, designing a joint home–school management plan, or referring the child for assistance outside school, may be more appropriate choices than individual school-based counseling, as discussed earlier.

Observations, interviews, and sometimes formal psychological assessment conducted by the likely counselor or another member of the psychological services team also may be needed to inform these decisions. The level of necessary assessment is determined, in part, by the nature and degree of severity of the problem the child is exhibiting. Informal assessment may provide enough information to determine the child's need for individual counseling. In other cases formal assessment may be necessary. Assessment information gathered at this stage also may be used as a pretest to provide the basis from which to develop goals and, during the course of individual counseling, to judge whether goals have been met.

During this first stage, the child's parents or guardians need to be contacted to gain information and, if the decision is made to pursue counseling, to obtain their permission. It is recommended that the school psychologist arrange to meet with the child's parents or contact them by phone to begin developing a relationship that is likely to be vital to the effectiveness of the counseling intervention. Parents can provide the school psychologist with important information about family, developmental, and cultural factors that could influence the success or failure of the counseling intervention. In addition, it is vitally important that the parents, teachers, and other important people in the child's life provide input that influences the counseling plan. Consideration should be given to their needs, viewpoints, and relationships with the child, and provisions need to be made for continuing communication with them during the course of counseling.

Stage 2: Plan for Counseling and Construct General and Specific Goals

To begin planning the counseling intervention, information gathered in Stage 1 provides the basis for understanding the child's needs. Viewing the child from a variety of theoretical orientations provides the basis for hypothesizing about underlying needs and for developing counseling goals and interventions. A theoretical framework, methods, and techniques that are appropriate for the child's difficulties and developmental level and are compatible with the personality and philosophy of the counselor must be chosen. The general counseling goals and methods chosen to attempt to meet those goals need to match the child's cognitive and emotional development. For example, the difficulty that young children have in taking another person's point of view or understanding abstract concepts must be considered when the plans for counseling with them are formulated. Additionally, possible cultural factors that may contribute both to the problem or to constructing an effective intervention should be considered (see, e.g., Vargas & Koss-Chioino, 1992). The level of intervention also must be considered at this stage. The level of intervention relates to the depth in which the counselor delves into emotional issues. Considerations about length of available time relative to the counselor's case load and the school year's end, as well as depth of intervention necessary to bring about positive change, are necessary.

Specific goals for the child may include lessening depression, anger, or anxiety; improving self-concept, interpersonal skills, or impulse control; or developing a repertoire of alternative appropriate behaviors for situations causing the child distress. The specific goals may be developed for the child within the school environment (such as reducing physical aggression in school or increasing participation in class) and within the home environment (such as increasing positive communication with parents or decreasing outbursts of anger at home). These specific goals would necessitate teachers' and parents' participation in modifying the environment, gathering data about the occurrences of behaviors, providing opportunities that make appropriate response by the child

TABLE 1
A Seven-Stage Model for Individual School-Based Counseling

Stage 1: Assess Appropriateness of Referral for Counseling
- Evaluate referral to judge appropriateness
- Consider alternative interventions to individual counseling
- Contact child's parents to obtain information
- Observe interview, and/or assess child
- Decide on individual counseling
- Contact child's parents to obtain permission, develop relationship, and gain input

Stage 2: Plan for Counseling and Construct Goals
- Use assessment data as pretest/basis for developing specific counseling goals
- Initiate counseling goals
- Determine framework and methods to be used
- Determine depth of counseling intervention

Stage 3: Begin Counseling
- Educate child about counseling
- Involve child in planning process
- Instill expectation of hope that counseling will benefit
- Provide feedback from assessment process
- Discuss confidentiality
- Discuss rules and limits

Stage 4: Establish a Working Relationship and Implement Plan for Change
- Work to develop counselor–child relationship
- Listen with empathy
- Make emotional connections
- Communicate understanding of emotions
- Offer emotional support
- Summarize, reflect, and be consistent in setting limits
- Maintain communication with parents, teachers
- Propose environmental interventions as necessary
- Be aware of one's own emotional reactions and seek assistance

Stage 5: Continue Counseling and Adjust the Plan for Change
- Reevaluate original plan and goals
- Administer interim measures and compare to pretest results
- Update goals and adjust methods
- Provide feedback to child, parents, and teachers

Stage 6: Assess Progress, Develop Plan for Termination, and Terminate
- Administer posttest measures and compare to pretest results
- Determine whether goals have been met and functioning stabilized
- Plan termination, providing adequate time for ending relationship
- Terminate counseling
- Provide feedback to parents and/or teachers

Stage 7: Evaluate Effectiveness of the Counseling Intervention
- Evaluate effectiveness of counseling intervention
- Write summary of initial assessment, counseling goals, course of counseling relationship, and evaluation of progress
- Follow-up with parents/ teachers about continued progress and needs

more likely, and providing positive reinforcers. The level of specificity, wording, and measurement of goals may differ according to the theoretical orientation of the school psychologist. Thus, the measurement of specific goals requires input from the child, teachers, and parents.

Stage 3: Begin Counseling

The primary work at Stage 3 involves preparing the child for the counseling intervention. Eliciting the child's knowledge, feelings, and beliefs about counseling in order to discuss them, and using developmentally appropriate language to share the initial goals and expectations, are part of preparing the child for counseling. It is desirable to give consideration to the child's needs, to involve him or her in the planning process, and to work at instilling an expectation of hope that counseling involves working together to remedy matters that are troubling to the child. It can also be very effective to provide the child feedback from the informal or formal assessment process. An approach taken by Fischer (1985) on individualizing assessment and providing meaningful feedback may be helpful.

Also at this stage guidelines concerning confidentiality need to be explained to everyone involved. Different counselors adopt different policies regarding this issue. For example, some share information with parents concerning the child's general progress while striving to keep the specific content of the counseling sessions confidential. Other counselors inform the child that the parents will have access to information from sessions, but agree to respect the confidentiality of any information the child specifically requests to be kept private. Whatever policy is adopted, parents' legal rights to information about counseling with their children and the legal obligation of counselors to take appropriate action if a threat of harm to the child or others is revealed needs to receive primary consideration. During the beginning phase of counseling, it also is appropriate to discuss limits and rules with the child, such as time and length of sessions and rules about breakage of toys, toy's remaining in the playroom, and the like. However, care should be taken not to overwhelm the child with a long list of rules. Often, limits are understood more easily when they are discussed as the occasion for them arises.

Stage 4: Establish a Working Relationship and Implement the Plan for Change

One of the primary bases for change in counseling lies in the development of the counselor–child relationship. The relationship provides the foundation for improvement and meeting the counseling goals. In order for progress to be made, a base of trust and security in the counseling relationship must be built. Guidelines for establishing the trust necessary for an effective counseling relationship can be found in several sources that discuss person-oriented approaches (Thompson & Rudolph, 1992; Wright, Everett, & Roisman, 1986). Listening with empathy, making emotional connections by striving to see and feel the child's world, communicating that understanding, and offering emotional support are essential to building a relationship of trust. Through trust, threatening feelings and thoughts can be examined and new ways of thinking, behaving, and relating can be attempted. Personal characteristics, such as warmth and the counselor's ability to be comfortable with the child's and her or his own thoughts and feelings, will help to establish the conditions necessary for building a relationship of trust with the child. Personal skills for establishing a working relationship with the child also include the ability to summarize, to reflect, and to be consistent, especially with respect to setting limits.

While developing a working relationship, the plan for effecting change is implemented. The qualities and skills used to build the relationship will continue to remain relevant throughout the course of counseling. Among the skills utilized by counselors in this and the following stages are the ability to play, to communicate a sense of humor, to use self-disclosure to promote the child's growth, to use interpretation to make connections among patterns and themes in the child's life, and to use confrontation when necessary. Techniques from various theoretical frameworks need to be implemented — for example, problem-solving strategies from a cognitive-behavioral orientation. It is necessary to maintain communication with parents, teachers, and others working with the child throughout the counseling process. Environmental influences on the child need to be noted and environmental interventions made when necessary. Rather than attempting to take over the roles of others in the child's life, the counselor should encourage the caring and competence of others in relation to the child.

Throughout the counseling process it is essential for the counselor to consider his or her feelings in relation to the child and others involved with the child. Careful and consistent attention to personal feelings will help to clarify emotional reactions related to the counseling relationship, to understand the child's feelings, and to understand the reactions of others to the child. It is common for counselors to experience emotional reactions in their professional relationships that echo past relationships. Awareness that this is happening can help the counselor react to the present child and situation rather than reacting blindly to remnants of past persons and situations. The counselor should not hesitate to arrange for consultation with a colleague if difficulties in understanding and managing emotions within the counseling relationship are encountered. The value that consultation with colleagues holds for improving the practice of school-based counseling cannot be emphasized enough. Awareness that results from meeting to discuss particular cases, theories, methods, techniques, and personal feelings in relation to a particular child is a vital part of one's development as an effective counselor.

Stage 5: Continue Counseling and Adjust the Plan for Change

During the course of counseling, a reevaluation of the original plan, the goals, and progress to date needs to be performed. Mistakes in planning, lack of understanding of the child's culture, changes in the child and the child's environment, and the counseling process itself make ongoing adjustment of the goals and methods that are chosen for counseling essential. Utilization of measures to determine progress and gather further information about the appropriateness of working hypotheses will aid in making decisions about effectiveness of methods and degree of progress toward goals. Periodically during the course of counseling feedback about the progress of the intervention (within the guidelines of confidentiality) needs to be given to the child, the parents, and others who work with the child. Feedback should be honest and be designed to maximize the potential for future improvement.

Stage 6: Assess Progress, Develop a Plan for Termination, and Terminate

In theory, counseling should end when goals have been met and the child's functioning has improved and stabilized. In practice, the decision to end counseling is seldom simple, or ideally planned. Partially met goals, lack of cooperation by significant persons in the child's life, a family move to another city, the psychologist's move to another school or job, and the end of the school year are often the primary reasons for termination of counseling. When few goals have been met and the child is not functioning well, more intensive counseling than the school is able to provide or an entirely different type of intervention may be necessary. If the goals have been met partially, enough progress may have been made so that interactions between the child and significant others are healthier, thus creating an environment more likely to support continued progress. To determine whether progress toward meeting goals has occurred, posttest measures similar to those initially used to develop goals need to be administered and the results compared with initial assessment results.

In planning for termination it is vitally important for the counselor to be sensitive to the significance that the relationship has for the child. Negative feelings, such as anger and sadness, may be evident at the termination of a meaningful relationship. Some children may experience problems associated with earlier separations and losses. Adequate time during the final counseling sessions should be taken to discuss feelings associated with ending the counseling relationship. Attention also should be paid to positive feelings associated with the child's improvement and plans for the future. Reassurances that the child will be remembered and exchanging keepsakes such as photographs, artwork, or stories written for the child are examples of strategies used by counselors to help the child manage feelings associated with termination. Gradual reduction of counseling time may be helpful in some situations, for example, by scheduling sessions every other week or once a month during the termination phase. Henderson (1987) and Schmukler (1991) thoroughly address the termination process with children and adolescents.

Stage 7: Evaluate Effectiveness of the Counseling Intervention

Systematic evaluation of the effectiveness of school-based counseling interventions is essential in order to improve counseling methods and outcomes (for further information, see Ehly & Dustin, 1989). Attention to concurrent interventions, environmental changes, case progress notes, data from pre- and postassessment measures, and measures of the child's behavior in natural contexts relative to the goals of the counseling intervention provides the information necessary for determining the extent to which counseling has been effective. After termination, a written summary of the precounseling assessment, the counseling goals, and the course of the counseling relationship, as well as an evaluation of the progress made by the child, need to be completed and placed in the appropriate records. Periodic follow-up with parents and/or teachers is recommended in order to trace the child's adjustment and progress after the counseling intervention has ended.

SUMMARY

Children are an underserved population with respect to their mental health needs. Multiple and coordinated interventions designed for children, their families, and their teachers are needed, and school psychologists can play a key role in the delivery of a continuum of school-based psychological services. The provision of individual school-based counseling is one piece of the complex response needed. Fortunately, there currently is a wealth of scholarly and pragmatic material available to the counselor to guide intervention efforts. This chapter presented a developmentally and culturally sensitive orientation to counseling, strongly influenced by a relationship model and strengthened by the therapeutic techniques of attachment, cognitive-behavioral, and systems theories. The adoption of a child–school–family philosophy, involving home and school caregivers in the counseling process, was emphasized throughout. Cultural considerations were strongly emphasized because of the need to provide more relevant services to children from minority groups. The unique and

challenging aspects of providing counseling to children in schools were discussed. The many elements necessary to the process of becoming, and developing as, a counselor were stressed, including: extensive education and training in a developmental perspective, cultural considerations, integration of theoretical models for counseling, pertinent research findings, play therapy psychopharmacology, and professional ethics. Finally, a seven-stage framework was offered as a step-by-step guide to *best practices* in school-based counseling with elementary-age children. School psychologists are challenged to integrate their knowledge, skills, and self development as they continue to address the extensive mental health needs of children in the schools.

ANNOTATED BIBLIOGRAPHY

Dennison, S. T. (1989). *Twelve counseling programs for children at risk.* Springfield, IL: Charles C Thomas.
This book presents the author's model for therapy practice, which combines several theoretical orientations but primarily derives from behavioral therapy. Process and content goals, as well as suggested means of attainment, are presented for both individual and group therapy. Additionally, presenting symptoms, treatments of choice, possible goals, assessment instruments, possible session themes, and suggested techniques are presented for twelve problem areas (school-related problems, low self-esteem, aggressive/acting-out problems, children in crisis, childhood depression, family life changes, children of substance abusers, sexually abused children, peer relationship problems, hyperactivity/short attention span, physically abused children, and neglected children). This book provides a variety of activity ideas for the beginning counselor.

James, B. (1989). *Treating traumatized children: New insights and creative interventions.* Lexington, MA: D. C. Heath.
This book provides an in-depth view of states that result from trauma and guidelines for treatment. The traumagenic states that are discussed and for which treatment is suggested include self-blame, powerlessness, loss and betrayal, fragmentation of bodily experience, stigmatization, eroticization, destructiveness, dissociative/multiple disorder, and attachment disorder. This book is an excellent source for both beginning counselors and those working with traumatized children.

Kissel, S. (1990). *Play therapy: A strategic approach.* Springfield, IL: Charles C Thomas.

This book provides a broad approach to play therapy that can be used by clinicians from a variety of theoretical orientations. Suggested techniques include the use of modeling, drawing, construction, cameras, computers, board games, storytelling, and relaxation. Specific activities make this book an excellent resource for the beginning counselor.

Spiegel, S. (1989). *An interpersonal approach to child therapy: The treatment of children and adolescents from an interpersonal point of view.* New York: Columbia University Press.
This book presents therapy from an interpersonal and developmental perspective. The use of play and metaphors is discussed, and a description of the course of therapy from initial sessions and limit setting to termination provides an easily read guide for the beginning therapist.

Vargas, L. A., & Koss-Chioino, J. D. (Eds.). *Working with culture: Psychotherapeutic interventions with ethnic minority children and adolescents.* San Francisco: Jossey-Bass.
Working with Culture discusses therapeutic issues and suggested intervention techniques when working with African American, Hispanic American, Asian American, and Native American children. It presents culture-related issues that affect therapy, including developmental and environmental perspectives (i.e., poverty, racism, acculturation, and normative behavior) and provides a model for understanding culturally responsive psychotherapies. This book is an excellent source for all counselors, especially those who work with children of culturally diverse backgrounds.

Best Practices in Transition Services

Edward M. Levinson
Indiana University of Pennsylvania

OVERVIEW

It is late one Friday afternoon in the dead of winter. The snow has just begun to fall as you leave Testa U. Child High School. You have just participated in a multidisciplinary staffing on Susan, a 16-year-old special education student who was due for her triennial reevaluation. You had first recommended that Susan be placed in a special education program when she was 10 years old, and this was the third time you had evaluated her. This evaluation was no different than any of the others: curriculum-based assessment results, standardized test scores, and observational and interview data continued to suggest functioning within the range of educable mental retardation; no evidence of social or emotional difficulties; recommendation for continued placement in the current special education class. The multidisciplinary team has relied heavily on you for program planning, and has accepted your recommendation for continued special education programming.

As you walk down the steps of the school, your thoughts begin to shift to your imminent week-long vacation to Hawaii. It is a vacation for which you had been preparing for years. As you begin to dream of white sand beaches and lais, you are interrupted by a coworker who has just participated with you in the staffing on Susan. Your colleague asks, "What do you think Susan's life will be like next year when she leaves school?" There is a bit of silence. "I don't know." There is more silence; then your colleague bids you farewell. Your mind wanders back to your work with Susan and then abruptly shifts to all the thought and effort that went into planning your vacation. Your mind wanders back to Susan and your stomach feels empty. What will happen to Susan . . .

Until recently, evidence suggests that for students with disabilities like Susan, little effort has gone into post-school planning. As Halloran (1989) has said:

> Some students reach the end of their public school experience poorly prepared for competitive employment or independent living. As students approach the end of their formal schooling, we frequently ask what they will be doing after school ends. Unfortunately, when we look back to determine what preparations have been made for students to live and work in our communities, we often see a series of disjointed efforts lacking a focus on skills necessary to confront the new expectations of adult life. (p. xiii)

Statistics clearly support Halloran's assertion. The President's Committee on the Employment of the Handicapped reports that following the completion of school, only 21% of persons with disabilities become fully employed, 40% will be underemployed and at the poverty level, and 26% will be on welfare (Pennsylvania Departments of Education and of Labor and Industry, 1986). Similarly, Rusch and Phelps (1987) have reported that 67% of persons with disabilities in the United States between the ages of 16 and 64 years are not working. Of those persons with disabilities who are working, 75% are employed on a part-time basis, and of those who are not employed 67% indicate that they would like to be employed. Similarly, statewide surveys in Florida (Fardig, Algozzine, Schwartz, Hensel, & Westling, 1985), Washington (Edgar, 1987), Colorado (Mithaug, Horiuchi, & Fanning, 1985), Vermont (Hasazi, Gordon, & Roe, 1985), and Nebraska (Schalock & Lilley, 1986) have indicated that the employment rate for persons with disabilities ranges between 45% and 70%, depending upon disability and geographical location. Between 64% and 82% of this population report living at home with a parent or guardian. According to Edgar (1987), 42% of learning-disabled and behaviorally disturbed students leave school before graduating, as do 18% of mentally retarded students.

More recently, the *Twelfth Annual Report to Congress on the Implementation of the Education of the Handicapped Act* (U.S. Department of Education, Office of Special Education and Rehabilitative Services, 1990) indicated that 47% of all students with disabilities do not graduate from high school with either a diploma or certificate of completion. These data are corroborated by Wagner and Shaver (1989), who found that 44% of students with disabilities failed to graduate from high school and 36% of students with disabilities dropped out of school. As Ysseldyke, Algozzine, and Thurlow (1992) report, studies that have compared special education dropout rates with control group dropout rates or normative data have consistently shown that students with disabilities leave school more often than students without disabilities.

More recent data corroborate these findings but suggest some encouraging trends as well. D'Amico and Marder (1991), in a longitudinal study that included a nationally representative sample of youths with disabilities out of school at least 1 month and no more than 2 years, reported that 52% of youths with disabilities were employed in 1987. However, this employment rate increased to 67% in 1989. Whereas employment rates increased in almost all disability categories, rates varied by disability category. While 67% of learning-disabled persons were employed in 1989, only 48% of emotionally disturbed, 56% of mildly and moderately retarded, and 10% of multiply handicapped persons were reported to be employed (Marder & D'Amico, 1992). In all disability categories other than learning disability with speech impairment, the employment rates of youths with disabilities was significantly lower than the employment rate of nondisabled youths (Marder & D'Amico, 1992).

There is little doubt that, given the high unemployment and underemployment rates among persons with disabilities, the high percentage who continue to live at home following the completion of school, and the elevated dropout rate among students with disabilities, efforts in the area of special education have not resulted in their successful integration into society. School psychologists, who have historically played an integral part in the special education process, must assume some responsibility for such a dismal state of affairs. Historically, school psychologists have had little involvement in the vocational or career planning of students with disabilities (Shepard & Hohenshil 1983; Levinson, 1988, 1990), despite the fact that they possess skills that, it can be argued, are critical to effective vocational planning, and despite the standards set by the National Association of School Psychologists (NASP, 1992). (For citation of these standards, see NASP [1992] or Levinson, this volume, on Vocational Assessment.)

In an effort to promote successful transition from school to work and community living, federal and state governments have made transition services a priority for all students with disabilities. In the landmark document "OSERS Programming for the Transition of Youth with Disabilities: Bridges from School to Working Life" Madeline Will, of the Office of Special Education and Rehabilitative Services, defined transition as follows:

> The transition from school to working life is an outcome-oriented process encompassing a broad array of services and experiences that lead to employment. Transition is a period that includes high school, the point of graduation, additional postsecondary education or adult services, and the initial years of employment. Transition is a bridge between the security and structure offered by the school and the opportunities and risks of adult life. Any bridge requires both a solid span and a secure foundation at either end. The transition from school to work and adult life requires sound preparation in the secondary school, adequate support at the point of school leaving, and secure opportunities and services, if needed, in adult situations. (Will, 1986, p. 10)

Will's document is the generic root from which transition programs have developed. In October 1990, Congress enacted the Education of the Handicapped Act Amendments of 1990 (Public Law 101—476), an amendment of PL 94-142, the Education of the Handicapped Act (EHA). Under this new law, the name EHA has been changed to the Individuals With Disabilities Education Act (IDEA). IDEA requires that transition plans be developed for all students with disabilities and be included in the students' IEPs by the time the students reach age 16. Section 602(a) of IDEA defines transition services as

> a coordinated set of activities for a student, designed within an outcome-oriented process, which promotes movement from school to post-school activities, including post-secondary education, vocational training, integrated employment (including supported employment), continuing and adult education, adult services, independent living, or community participation. The coordinated set of activities shall be based upon the individual student's needs, taking into account the student's preferences and interests, and shall include instruction, community experiences, the development of employment and other post-school adult living objectives, and, when appropriate, acquisition of daily living skills and functional vocational evaluation. (Education of the Handicapped Act Amendments of 1990, pl 101-476, Section 602(a) [20 USC 1401(a)]

PL 101-476 requires that a student's IEP address the issue of transition and that transition planning be initiated by at least age 16. Specifically, IDEA lists the following additional requirements for the IEP:

> . . . a statement of needed transition services for students beginning no later than age 16 and annually thereafter (and, when determined appropriate for the individual, beginning at age 14 or younger), including when appropriate, a statement of the interagency responsibilities or linkages (or both) before the student leaves the school setting, and . . . in the case where a participating agency, other than the educational agency, fails to provide the agreed-upon services, the educational agency shall reconvene the IEP team to identify alternative strategies to meet the transition objectives.

BASIC CONSIDERATIONS IN TRANSITIONAL PROGRAMMING

While the professional literature has generally treated transition planning separately from vocational assessment, the two are intimately related. Successful transition planning cannot occur without the information gleaned from a comprehensive, functional, vocational assessment. Conversely, vocational assessment data have little value if they are not used to recommend services designed to facilitate successful transition from school to work and community living. Given the clear relationship between vocational assessment and transition planning, it makes little sense to discuss each separately. Transition planning should be embedded in an overall vocational assessment and planning model. The transdisciplinary vocational assessment (TVA) model advocated by this author (Levinson, 1993) and discussed in the chapter on vocational assessment elsewhere in this volume essentially integrates the two processes. The data gathered through TVA can be used to recommend the services a student needs to make a successful adjustment to work and community living. Based upon the results of the TVA, a transition plan can be developed and included in a student's individual education plan.

As to the information needed by a school psychologist or other school professional to facilitate the transition process of students with disabilities, one must first consider what skills the student needs to adjust to community living and to obtain and maintain employment. Generally, these skills can be broken down into three major areas: *daily living skills*, *personal/social skills*, and *occupational/vocational skills* (Wehman, Moon, Everson, Wood, & Barcus, 1988). The daily living skills that are necessary for independent living include managing finances, maintaining a home, caring for personal needs, buying and preparing food, buying and caring for clothing, engaging in recreation and leisure pursuits, and being mobile within the community. Personal/social skills include maintaining hygiene and appearance, accepting praise and criticism, and exhibiting situationally appropriate behavior, appropriate interpersonal skills, adequate problem-solving skills, and adequate communication skills. Occupational/vocational skills include understanding and exploring occupational and vocational alternatives, exhibiting appropriate work habits and behaviors, possessing marketable vocational skills, and exhibiting appropriate job-seeking skills. The assessment of these areas, in addition to those traditionally assessed by school psychologists, is especially critical to the development of a transition plan.

Having identified the individual needs of a particular student and having determined the particular skills that this student needs to learn to make a successful transition, school personnel must structure the educational curriculum accordingly. Generally, this will involve the development of a "functional curriculum." A functional curriculum is one in which the goals and objectives are based upon the demands of adult life across a variety of settings (Wehman et al., 1988). In such a curriculum, the particular skills a student lacks across the domains cited previously (daily living, personal/social, occupational/vocational) are taught in a way that enables the student to utilize them in the workplace, in leisure and residential settings, and in community facilities. Given the difficulty that persons with severe disabilities have in generalizing skills across settings, it is sometimes necessary to conduct instruction appropriate to a particular setting in that setting itself. Consequently, professionals involved in transition services must be familiar with residential and community-based educational programs. For more information on Life-Centered Career Education, Functional Community-Based Special Education, Work Adjustment, Training Programs, and other organized programs designed to accomplish the goals listed above, the reader is referred to Levinson, Peterson, and Elston (in press).

Knowledge of local employment options available for individuals with disabilities is also necessary for professionals developing transition plans for students. Generally, the options include *competitive employment*, *supported employment*, and *sheltered employment*. The appropriateness of each of these employment options for a particular student depends upon that student's individual skills. Competitive employment options are those in which individuals are placed in competitively salaried community jobs without the provision of ongoing support services. Supported employment options are those in which individuals are placed in jobs with special assistance from "job coaches" who provide ongoing support (including training, retraining, problem resolution, etc.). Sheltered employment options are those in which individuals are placed in businesses operated by human service agencies (typically termed *sheltered workshops* or *work activity centers*). The various residential options that are available for persons with disabilities in the community must also be considered by transition personnel when planning for students. Residential options may include independent living in single-family or group homes and apartments, living with family or friends, foster homes, nursing homes, and other private and public residential facilities. Again, the appropriateness of each of these alternatives will be determined by the unique needs and circumstances of each student.

Finally, school psychologists and other professionals involved in transition services must be knowledgeable about the support service agencies in the local community, and they must understand the nature of the services provided by these agencies and the extent to which these agencies can assist in the transition process. As will be discussed shortly, the transition process involves a variety of school and community professionals working together as a team to provide for the needs of persons with disabilities. To the extent that various team members understand, respect, and utilize the expertise and services provided by one another, the transition process will be greatly facilitated.

BEST PRACTICES IN TRANSITION PROGRAMMING

Components of Effective Transition Programs

Halloran (1989) suggests that effective transition programs have three essential components: (a) The program involves the families of persons with disabilities as equal partners in planning and implementing activities that are designed to facilitate independent functioning; (b) the program is community-based, providing persons with disabilities with opportunities to succeed in employment and other aspects of community life; and (c) the program is based upon working partnerships among schools, businesses, and community agencies. Additionally, effective programs ensure that planning for postschool adjustment begins early in a student's educational career; that written, individualized plans specifying transition services are a part of each student's IEP; that attempts are made to integrate persons with disabilities with persons without disabilities; that the educational curriculum focuses upon instruction of relevant and functional life skills; and that a large part of instruction takes place in the community.

Development of Transition Programs

As has been suggested earlier, transition programming involves a variety of school and community professionals. Consequently, the initial step in developing a transition program at the local level is to identify, organize, and mobilize these various professionals and agencies. Wehman et al. (1988) advocate the establishment of a local core transition team to include such professionals as a special education administrator, a vocational education administrator, a vocational rehabilitation administrator, the director of mental health/mental retardation, a developmental disabilities planning council member, and a parent and/or client advocate. According to Wehman et al. (1988), this local core team has the responsibility of conducting a needs assessment to determine the extent to which existing school, employment, and adult service programs are capable of providing the services which persons with disabilities require to make a successful transition from school to community living. For example, school programs must be evaluated to determine the extent to which educational/vocational programs are providing students with the skills necessary to obtain employment available in the local community. Employment programs must be evaluated to determine the extent to which they are successful in placing persons with disabilities in jobs. Adult service programs must be evaluated to determine the type of vocational assessment and postsecondary training services that are provided and the availability of supported and sheltered employment opportunities. The quality of community living arrangements, transportation, recreational and leisure programs, and medical and psychological services that are available in the local area must also be evaluated.

On the basis of the needs assessment data that are gathered, the team recommends improvements in school and community services and begins developing transition planning procedures. Decisions such as the age at which to begin formal transition planning, the types of students to receive transition services, the professionals to be involved in transition planning, the roles of these professionals, and so forth are made by this local core team.

A major responsibility of the core planning team is to establish formal, written interagency agreements, which have the purpose of further defining the various roles school and community agencies will assume in transition programming. Because many such interagency agreements have been developed at the state level, these should be reviewed and considered when local agreements are developed. According to Wehman et al. (1988), the core team identifies and verifies participation of key agencies and organizations, establishes flow patterns of handicapped students across local agencies and organizations (i.e., when a particular student is likely to be serviced by a particular agency and the nature of the services likely to be provided), and identifies the means by which services will be evaluated.

Individualized Transitional Programming

Once interagency agreements have been established that specify the kinds of transition services to be provided by the various agencies (school and community) involved and the population to whom these services are provided, individual transition programming can be initiated. According to Wehman et al. (1988), the first step in implementing this programming is to set up individual transition planning teams (ITPTs) for all students for whom plans are to be developed. Both school and community agency personnel participate on these teams. Appropriate school personnel include teachers (regular, special education, and vocational education), counselors, psychologists, and administrators. Representatives from community agencies such as mental health/mental retardation, vocational rehabilitation, and social services also participate on the ITPT. Parents need to be involved in these meetings, since research has indicated that parental participation increases the effectiveness of transitional services (Hasazi et al., 1985; Schalock & Lilley, 1986).

Since an overlap obviously exists between the school professionals who are involved in development of the student's individual education plan and those who are to be involved in transition planning, it makes sense to conduct transition planning as a part of annual IEP meetings for students with disabilities (as stated previously, PL 101-476 now requires that IEPs address transition by age 16). At a certain designated point during a student's educational career (the point at which transition planning is to be initiated, and no later than age 16), the IEP team should be expanded to include relevant community agency personnel. Although the age at which transition planning should begin is debatable, it is the author's opinion that it should be initiated at least 4 years before the student leaves school. In that the transition planning process for students with severe disabilities may be more involved and time-consuming than it is for other students, transition planning should probably be initiated earlier in the educational career of these students.

Roles for School Psychologists

It is likely that school psychologists will become increasingly involved in transition planning as a result of their extensive involvement in the assessment and programming of students with disabilities. Although the specific role that school psychologists will assume in the process is still undefined, it is clear that the skills possessed by school psychologists are critical to the development and implementation of successful transition plans.

At the present time, a variety of professionals assume major responsibility for the development and implementation of transition programs. Although no agreement currently exists as to who should assume this major responsibility, there are a number of "transition specialist" training programs for professionals with such titles as job coach, individual living specialist, supported employment, specialist, rehabilitation counselor, and special education teacher. The competencies acquired in these programs clearly overlap with the knowledge and skills of school psychologists. In their study of the competencies taught in 13 university "transition specialist" training programs across the country, Baker, Geiger, and deFur (1988) found that general knowledge of learning theory (particularly behavioral theory) and assessment were areas in which an extensive amount of training was concentrated. Both Baker et al. (1988) and Marinelli, Tunic, and LeConte (1988) agree that adolescent psychology is a frequently omitted but important area in the training of transition specialists. Clearly, the school psychologist's expertise in assessment, learning and behavior theory, and adolescent psychology may be particularly useful in transition planning.

From an assessment perspective, school psychologists have much to contribute to transition planning. As mentioned previously, particularly important in transition planning will be evaluation of interpersonal and social skills, independent living skills, and vocational skills. School psychologists working at the secondary school level may wish to alter their assessment strategies somewhat in order to emphasize these areas. For example, school psychologists might choose to incorporate measures of vocational interests and aptitudes and social skills (through interviews, observations, and paper-and-pencil tests) into their assessments. A number of time- and cost-efficient procedures for gathering this information are available to school psychologists and are discussed elsewhere (Levinson, 1993; Kapes & Mastie, 1988). Likewise, school psychologists might also wish to incorporate an evaluation of functional living skills into their assessments. An instrument such as the Social and Prevocational Information Battery (Halpern, Rafeld, Irvin, & Link, 1975) provides functional skills assessment data that can be utilized in transition programming.

School psychologists' knowledge of learning and behavior theory and of adolescent psychology allows them to serve as effective consultants to teachers (regular, special education, vocational education), rehabilitation counselors, job coaches, and employers relative to the conditions under which optimum learning and performance might be attained. Because a substantial amount of training may occur outside the school in job, community, or residential settings, school psychologists will have to prepare themselves to provide consultative services in settings other than the office or classroom. As a consultant, the school psychologist may also function as a liason among parents, other team members, community service agencies, and employers; or, in some cases, they may actually initiate the development of transition planning.

Other roles for school psychologists in the transition process are direct intervention, in-service, and research. From a direct intervention perspective, the school psychologist can facilitate transition by initiating development of social skills training programs. Such programs might be most effective when implemented in residential, community, or employment settings. School psychologists might conduct in-service workshops on the use of assessment data in transition programming for those involved in the development of transition plans, and on basic issues in adolescent psychology or learning for those professionals involved in direct training of skills necessary for successful transition. Finally, the effectiveness of the various programs designed to promote acquisition of the skills required for successful transition needs to be determined and the success that local school and community services have in facilitating the transition of students from school to work and community must be evaluated.

SUMMARY

As the final impact of recent federal legislation aimed at facilitating the transition between school and adult living is realized, it is likely that an increased number of school psychologists will become involved in transition planning. School psychologists, working as part of a transition team comprised of both school and community professionals, will need to upgrade their knowledge of vocational and independent living skills assessment, functional curricula, and community-based education; as well as the various employment and residential options available in their local community. Although the exact role school psychologists will assume in transition planning is still undefined, their assessment, counseling, consultation, and research skills will prove to be valuable assets to the development, implementation, and evaluation of transition programs.

ANNOTATED BIBLIOGRAPHY

Brolin, D.(Ed.). (1986). *Transition from school to work and adult life.* Columbia, MO: Division on Career Development, Council for Exceptional Children.

This volume, which contains abstracts of more than 80 projects, curricula, teaching methods, and transition models, is a useful reference guide for professionals and parents interested in the development of transition programs.

Levinson, E. M. (1993). *Transdisciplinary vocational assessment: Issues in school-based programs.* Brandon, VT: Clinical Psychology Publishing Co.

This book presents a model that integrates the vocational assessment and transition planning processes and discusses the development of such a program from both a theoretical and practical perspective. Six school vocational assessment program models are described, as are the roles of curriculum-based and community-referenced assessment in vocational and transition planning. The book addresses the use of assessment data in vocational and transition planning and includes sample forms that can be adapted for use in programs. A bibliography of references for professionals is also included.

McCarthy, P., Everson, J. M., Moon, S., & Barcus, J. M. (Eds.). (1985). *School-to-work transition for youth with severe disabilities.* Richmond: Virginia Commonwealth University, Project Transition Into Employment.

This compendium of articles by various authors describes step-by-step procedures for the development and implementation of transitional programs for severely handicapped students.

Best Practices in Counseling Programs for Secondary Students

Pauline M. Pagliocca

Steve R. Sandoval
University of Nebraska–Lincoln

OVERVIEW

School Psychologists and Counseling

At the secondary level, school psychologists function in a variety of professional roles such as psychoeducational evaluator, consultant, student services coordinator, community liaison, in-service trainer, and supervisor. In addition to these traditional roles, practitioners report that they are increasingly being called upon to provide individual and group counseling services to students (Huebner, 1993). As with other areas of practice, psychologists not only provide direct service to pupils but also participate in the design, development, and evaluation of counseling programs.

At the same time that many academic trainers are advocating an indirect/consultative services model in the schools (e.g., Conoley & Gutkin, 1986; Elliott & Witt, 1986), practitioners in the field, such as principals (Hartshorne & Johnson, 1985), special education directors (Cheramie & Sutter, 1993), and school psychologists themselves (Huebner, 1993) are calling for school psychologists to play a more active role in student counseling. Despite such interest in "psychologists as counselors," time and skill demands often preclude school psychologists from providing counseling directly to the number of students in need. But psychologists need not choose one end of the direct–indirect continuum over the other. Instead, they can apply their skills at multiple levels of any comprehensive counseling program.

Whether directly involved in student counseling or designing a school's counseling agenda, psychologists can expect their activities to interact and overlap with other professionals in the system. School counselors, social workers, administrators, nurses, and teachers are involved in counseling initiatives (Ehly & Dustin, 1989). And, increasingly, community mental health professionals and paraprofessional volunteers are delivering their services in school settings. Thus, school psychologists will not necessarily enjoy a "unique" role within a counseling program; rather, they can expect to share responsibilities with colleagues equally (and sometimes better) qualified to counsel adolescents and develop school- and system-wide counseling programs.

Use of this Chapter

School psychologists may wish to consult this chapter when considering the counseling needs of students, families, and professionals in their particular schools and the array of program components necessary to meet those needs. No survey of counseling or psychotherapy theories will be provided; other sources (e.g., Corsini & Wedding, 1989) offer more comprehensive and detailed information than can be included here. This chapter also will not advocate any particular approach to intervention; reviews of child and adolescent psychotherapy outcome research (Casey & Berman, 1985; Kazdin, 1990) offer little support favoring any one theoretical model (e.g., psychodynamic, cognitive-behavioral) or method (e.g., individual, group, family) of treatment. Instead, this chapter will discuss the expanding counseling role assumed by many school psychologists and will emphasize the importance of actively collaborating in the development of comprehensive counseling programs at the secondary level. Consistent with the position that school psychologists comprise but one profession involved in counseling secondary school students, the generic term "counselor" will be used throughout this chapter in reference to any professional providing such services in school settings. Finally, this chapter will present a broad range of issues for consideration in determining whether to counsel, who should counsel, and what the scope of the total counseling program should be.

BASIC CONSIDERATIONS

Counseling or Psychotherapy?

When assisting students with emotional and behavioral difficulties, do school psychologists practice *counseling* or do they practice *psychotherapy?* How easily can distinctions be made between the two endeavors? And is it important to do so? A comparison of Patterson and Eisenberg's (1983) account of "counseling" with Kazdin's (1988) description of "psychotherapy" illustrates the difficulties inherent in attempting to differentiate clearly between the two and suggests that dwelling on carefully crafted definitions may not lead to any notable distinctions in actual practice.

> *Counseling* [italics added] is an interactive process characterized by a unique relationship between counselor and client leading to change in the client in one or more of the following areas: (1) Behavior; (2) Personal constructs (ways of construing reality, including self) or emotional concerns relating to these perceptions; (3) Ability to cope with life situations so as to maximize opportunities and minimize adverse environmental conditions; (4) Decision-making knowledge and skill. (Patterson & Eisenberg, 1983, p. 22)
>
> *Psychotherapy* [italics added] consists of a special interaction between two (or more) individuals where one person (the patient, or client) has sought help for a particular problem, and where another person (the therapist) provides conditions to alleviate that person's distress and to improve functioning in everyday life. The interaction is designed to alter the feelings, thoughts, attitudes, or actions of the person who has sought or has been brought to treatment. (Kazdin, 1988, p. 1)

Obviously, it is difficult to determine where counseling ends and therapy begins. In fact, with the growing popularity of interventions such as short-term therapy, cognitive-behavioral counseling, solution-focused therapy, parent education, and various types of support groups, distinctions once considered informative may no longer serve any useful function. Thus, throughout the remainder of this chapter, the terms "counseling" and "therapy" will be used interchangeably. Generally, however, most school intervention literature relies on the term "counseling," irrespective of the particular discipline or theoretical orientation of the practitioner.

Who Provides Counseling?

Many personnel are involved in counseling in schools. Generally, however, three groups — school psychologists, counselors, and social workers — provide the majority of such services. While acknowledging overlap in functions, Sandoval and Davis (1992) argue for a "unique" counseling role for the school psychologist: "crisis counseling, brief counseling, brief family therapy, vocational counseling for special education children, and social and other skills training" (p. 245). The only support they offer, however, is the extended length of training for the school psychologist, without further reference to any particular component of training (e.g., specialized counseling course work) that would qualify the psychologist in any of these areas.

Humes and Hohenshil (1987) approach the "uniqueness" issue from a different perspective. While acknowledging certain differences in expertise (e.g., the school psychologist's preparation as a diagnostician), they highlight similarities in training and actual practice which are applicable to the question of who should provide counseling services in the schools.

> All these personnel [counselors, school psychologists, and social workers] provide counseling services, are involved in primary mental health prevention, assist in curricular adaptations for individual pupils, and engage in outcome-oriented efforts to evaluate the productivity of the helping relationships. (Humes & Hohenshil, 1987, p. 39)

Like the blurred lines between counseling and psychotherapy, role distinctions based on professional discipline may reflect little of the actual practice of psychosocial treatment in secondary schools.

Rather than professional identity, the primary criterion for determining who should provide therapeutic services should be competence. That is, who is qualified to provide a particular type of intervention to a specific student or group of students? Both the American Psychological Association (APA, 1992) and the National Association of School Psychologists (NASP, 1992) suggest "competence" as a basic ethical principle in guiding psychological practice. Thus, one school psychologist may be competent to provide crisis counseling while another is not. Training (or certification) as a school psychologist does not, *per se*, qualify an individual to provide any particular form of intervention. The experience of the individual counselor should determine who provides services.

An emphasis on competence, rather than on profession-determined roles, suggests the need for cooperation and collaboration at both the building and system levels. The various counseling professions must work together as a team, assessing their collective competencies and determining areas for further professional development. By functioning in this way, they will be more likely to address effectively the counseling needs presented by their students.

Characteristics of School-Based Counseling

School-based counseling involves several characteristics which differentiate it from interventions practiced in other settings, such as community mental health centers or the offices of private practitioners. Maher and Springer (1987) provide a useful summary of "distinguishing features":

> 1. School-based counseling provides an opportunity to counsel students in a natural setting.

2. It is provided over a finite period of time and within circumscribed time parameters.

3. It is targeted to a clearly defined set of school-related goals.

4. It can be provided in one-to-one or in group modes.

5. It can be provided by a range of different school personnel.

6. It has limited confidentiality.

7. It involves assisting some involuntary clients. (p. 101)

Such school-based treatment also focuses on changing school and family systems and allows an opportunity for early intervention in many cases. Although not all school personnel agree that mental health intervention should take place in the schools, often this is an ideal setting for providing direct service to troubled children and families. In many communities (both urban and rural) few other services are available or accessible, parents may not avail themselves of those that do exist (Sandoval & Davis, 1992), and parents and adolescents may view involvement in school services as less stigmatizing than those offered in other public settings. Thus, students and parents may be more likely to actually follow through on referrals and *participate* in school-based intervention services.

Comprehensive Counseling Programs

General approaches to counseling in the schools. Textbooks on school counseling vary in their presentations of approaches to counseling. Some focus on program components while others describe a range of theoretical approaches to intervention. Myrick (1987) described four general approaches to guidance and counseling used in school settings: (a) *crisis*, (b) *remedial*, (c) *preventive*, and (d) *developmental*. "Each approach has a salient theme which influences program direction, the type of services provided to students, and how professional personnel spend their time" (Myrick, 1987, p. 11). Although counseling programs often incorporate all of these approaches to some extent, it is likely that, without careful planning and coordination, a particular approach will dominate, leaving only limited time and resources for the others. A comprehensive counseling program at the secondary level should include all of these approaches.

- *The crisis approach.* In the crisis approach to counseling, the focus is usually short-term (sometimes involving only one session) and specific to defusing the immediate danger or threat. This orientation is all too familiar to experienced school psychologists. Programs dominated by this approach respond to students and staff only when problems have escalated to the point of jeopardizing individual psychological and/or physical welfare. While all programs must develop the capacity to respond to crisis situations, those that rely on this as the primary scheme are likely to be costly, inefficient (Myrick, 1987), and guilty of allowing problems to reach a crisis level before warranting a response. In the meantime, other students and problems may be ignored. Interestingly, as Myrick points out, "while counselors complain that they do not have time to see all the students who need their help, there is always time to react to a crisis" (1987, p. 13).
- *The remedial approach.* In the remedial approach, perhaps the most common in school counseling programs, specific academic or psychosocial needs of the student body are identified. Intervention strategies are then designed and implemented in an effort to avoid repeated, but predictable, crises (see Myrick, 1987). For example, a series of counseling groups may be established in response to a large number of students being identified as having problems in day-to-day social interaction with peers. Referral to the group program, then, would be based on identified deficits in social skills with the goal of making up for such deficiencies. Counseling programs dominated by the remedial approach involve more planning than those with a primarily crisis orientation, but generally, they still operate in a reactive mode.
- *The preventive approach.* As in other areas of mental health, the preventive approach has enjoyed much popularity, if not demonstrated success. This approach relies on considerable planning and anticipation of student and staff problems. It places the counseling staff in a more favorable position, compared to those operating in a primarily reactive mode. Unfortunately, the list of what should be prevented could be endless (Myrick, 1987) and subject to political pressures from the most vocal elements of the school community and to which "causes" are most popular at a particular time. And as Myrick suggests, the preventive approach "concentrates on what we do not want (e.g., drug abuse, violent behavior, poor study habits), instead of what we do want to happen" (1987, p. 15).
- *The developmental approach.* The developmental approach to guidance and counseling (e.g., Gysbers & Henderson, 1988), while perhaps unfamiliar to many school psychologists, has played a prominent role in the training and experience of school counselors. This approach includes the other three (i.e., crisis, remedial, and preventive) and views the guidance and counseling "curriculum" as complementing the academic curriculum. Such a comprehensive counseling program "attempt[s] to

identify certain skills and experiences that students need to have as part of their going to school and being successful" (Myrick, 1987, p. 15). Schools that develop comprehensive counseling programs, such as those suggested by the developmental approach, are able to provide "counseling" by integrating it into the academic curriculum as well as by providing more specialized interventions.

Essential services of a comprehensive counseling program. The term "counseling" usually brings to mind a picture of an adult professional meeting with one or more troubled individuals to discuss and work toward solutions to identified or suspected problems. Such activity would constitute only one service, however, in a comprehensive counseling program. Schmidt (1993) identified four major components of such a program:

1. *Counseling* — individual and group, with students, parents, and teachers.

2. *Consulting* — including individual student planning, classroom guidance, parent education, and teacher in-service.

3. *Coordinating* — data collection and sharing, referrals and follow-up, and school-wide events and programs.

4. *Appraising* — individual, group, and family assessment including testing, observations, and interviews.

While schools may provide all of these services, frequently they are offered through separate departments or divisions of the school district, resulting in overlapping (and sometimes uncoordinated) services to the same students and staff. In a comprehensive counseling program, all four components are considered essential and offered in a single agenda rather than as separate, or even interconnected, pieces.

When is Counseling Warranted?

Adolescents whose "behavioral, cognitive, emotional, and/or interpersonal functioning causes them or others distress and interferes with their development and learning" are those likely to be referred for counseling (Tharinger & Koranek, 1990, p. 407, regarding younger children). In addition, students experiencing academic problems are frequently referred by teachers and administrators in an attempt to "fix" such problems. Counselors are then in a position to determine if counseling, rather than other forms of intervention such as consultation with the classroom teacher or remedial instruction, is warranted and likely to be the most appropriate means of addressing identified or suspected problems. A scheme for classifying problems which may lend themselves to counseling intervention is discussed more fully below.

Ethical and Legal Concerns

Counseling inevitably involves ethical and legal questions that must be addressed by individual counselors as well as program developers. While professional organizations provide ethical principles and standards of practice as guidelines for their membership (e.g., APA, 1992; NASP, 1986, 1992), each state applies its own statutes and regulations governing professional conduct. Sometimes, laws that apply to practitioners in private practice may not apply directly to those operating in public schools. Similarly, statutes and regulations governing the practice of "licensed" psychologists may not extend to "certified" school psychologists. For example, a state which grants a right of "privileged communication" to treatment with licensed psychologists may not extend this same privilege to treatment with a certified, but not licensed, school psychologist. (Privileged communication has been defined as "those statements made by certain persons within a protected relationship such as husband–wife, attorney–client, priest–penitent ... which the law protects from forced disclosure on the witness stand at the option of the witness, client, penitent, spouse" [Black, 1991]. In some states, this privilege may also apply to the psychotherapist–client relationship. The privilege belongs to the client, not to the professional.) When this is the case, such a distinction should be made clear to any client. In addition, individual school systems develop specific policies related to the ethical and legal practice of all school staff, including psychologists. Given this variety of rules that may direct, as well as limit, the scope of practice, it is imperative that school psychologists become thoroughly familiar with all that apply to them.

Although this chapter advocates cross-disciplinary collaboration in the provision of counseling services, it must be made clear that the law may not operate from such a perspective. Instead, psychologists will be expected to adhere to laws and ethical principles governing the professional behavior of *psychologists* and not those of any other related profession, regardless of the specific activities they undertake.

Written policies and procedures and in-service education for all staff may well be the best vehicles for ensuring that counseling-related policies are developed and followed. For example, all staff should be aware of the system's policies related to confidentiality and its limitations, parental notification, feedback to classroom teachers, voluntary participation in counseling, emergency hospitalization, and reporting of suspected child abuse. Procedures should not be determined on a case-by-case basis but should follow from the guidelines established in the development of the overall counseling program as well as from state statutes and regulations governing professional practice in each of these areas.

School Psychologists' Training in Counseling and Program Development

Related to ethical practice, counseling should be provided only by those professionals with the appropriate preparation to do so. "School psychologists, provided that they possess the necessary education, training, and supervised experience, are in an excellent position to help identify [students in need of counseling] and, if appropriate, to offer them counseling services" (Tharinger & Koranek, 1990, p. 407). But are school psychologists adequately prepared to provide counseling at the secondary level?

When surveyed, practicing school psychologists repeatedly report that they have received insufficient training in counseling in general and in counseling secondary students, in particular (e.g., Carroll, Bretzing, & Harris, 1981; Huebner, 1993). And yet they are increasingly expected to provide counseling services (Fisher, Jenkins, & Crumbley, 1986; Hartshorne & Johnson, 1985; Huebner, 1993). Consequently, when called upon to provide individual or group counseling to adolescents, many school psychologists may be not only ill-prepared but also at risk of crossing the ethical bounds of their professional competence.

The findings of the surveys cited here support the arguments of Curtis and Batsche (1991) that in order for psychologists to be prepared to work effectively at the secondary level, school psychology programs may need to increase the level of training in direct intervention services with adolescents. Practicing school psychologists must also avail themselves of course work and training in approved programs, as well as supervised experience, in order to meet clinical, ethical, and legal obligations when delivering counseling services to students.

In addition to direct services, psychologists are frequently involved in the design, development, and evaluation of counseling programs in school settings. But again, field surveys reveal that school psychologists receive limited preservice training in program development and evaluation (e.g., Huebner, 1993; Moore & Carlson, 1988) and see this as an important training need of secondary school practitioners (Huebner, 1993). Graduate programs should attend to this feedback from experienced practitioners in modifying and improving training curricula and standards.

Problems Faced by Contemporary Adolescents

Recent research shows that the number of stressors for children has increased substantially over the past two decades, and once children make the transition into adolescence, that number increases dramatically (Simmons & Blyth, 1987). Today's adolescents face a host of psychosocial problems that reflect the rapid pace of societal change (Barona & Garcia, 1990). Secondary students, themselves, identify numerous school-related sources of stress, ranging from difficulty of classroom tests (Bauwens & Hourcade, 1992) to interpersonal aggression (Armacost, 1989). In one study, the stressors of greatest concern to students were the ability-grouping system, the need to keep up with school work while holding a job, and theft of personal belongings (Armacost, 1989).

Given the pressures perceived by adolescents, which issues might psychologists anticipate addressing in developing and providing counseling services in secondary schools? A study conducted by Hutchinson and Reagan (1989), noting the most common problems for which high school seniors seek counseling services in school, suggests some answers to this question. They found that high school students seek counseling for a host of concerns, many of which might be addressed by school psychologists (see Table 1). Given the nature and variety of problems today's adolescents face, school personnel must be prepared to meet such needs by providing a range of services in the school setting.

Consistent with the notion that school problems reflect society's problems (Packard, 1983), psychologists might also anticipate issues of sexual orientation, ethnic/cultural identity, and gender equality in developing and providing counseling services at the secondary level. Contemporary authors have provided insight into the specific stressors that many homosexuals (Rotheram-Borus, Rosario, & Koopman, 1991), adolescents of color (Sandoval, Gutkin, & Naumann, 1994; Smith, 1986) and females (Dornbusch, Mont-Reynaud, Ritter, Chen, & Steinberg, 1991) must confront in a society which many experience as oppressive. Such marginalized students are expected to adjust to traditional school settings and expectations, and likewise, schools must accommodate and adjust to students who do not fit neatly into the mainstream.

Rotheram-Borus et al. (1991) maintain that gay and lesbian youth experience stress from the fear that their sexual orientation will be discovered by family and friends or cause significant others to "disown" them and that "coming out of the closet" will create chronic stress. In fact, one- to two-thirds of homosexual youths have reported experiencing stressors directly related to their sexual orientation (Dornbusch et al., 1991).

Among adolescents of color, the stressors are numerous as well. For example, Hale-Benson (1986) observed that, on the one hand, the "emphasis of traditional education has been upon molding and shaping Black children so that they can fit into an educational process designed for Anglo-Saxon middle class children" (p. 1), but on the other hand, they have to deal with pressures from their own cultural group to avoid "acting White" (Fordham & Ogbu, 1986). For many students of color, this potential clash between the demands of mainstream culture and those of their own ethnic group may lead to mental, emotional, and so-

TABLE 1
Rank Order of Issues for Which High School Seniors Would Seek Counseling Services

Rank	Reason	Percentage
1	Information about college, etc.	89.6
2	Graduation requirements	89.1
3	Registering for classes	89.0
4	Assistance in changing a class	87.3
5	Information about career opportunities	83.5
6	Scholarships/financial aid	81.0
7	Interpretation of test results	74.6
8	Deciding on a career	68.8
9	Assistance in job hunting	62.2
10	Conflicts with teachers	61.3
11	Orientation to a new school	60.9
12	Discipline problems	55.8
13	Truancy problems	47.0
14	Awareness of feelings and values	45.6
15	Alcohol or drug education	41.6
16	Conflicts with peers	39.6
17	General personal problems	39.5
18	How to get along in life	34.2
19	Alcohol or drug problems	33.3
20	Sexual, physical, or emotional abuse	32.2
21	Conflicts with parents	30.7
22	Relieving tension	26.5
23	Boyfriend/girlfriend relationships	19.5
24	Questions about sex	11.1

Note. Based on Hutchinson and Reagan (1989, p. 277). Rank order indicates the percentage of students checking either "Strongly Agree" or "Agree" to each item.

cial stress that warrants attention from school counseling personnel (Sandoval et al., 1994).

With regard to gender equality, Rosser (1990) pointed out that economic and social structures, including schools, suppress female students' achievement, self-worth, and self-esteem. For example, according to the recent report by the American Association of University Women (AAUW, 1993), many U.S. schools do not encourage female students to pursue science, mathematics, or other disciplines that are typically male dominated; sexual harassment of girls by boys has increased at an alarming rate; and female students do not receive as much attention from their teachers (male and female) as do boys. As a result, the AAUW posited, many young high school women lag behind their male counterparts in confidence and self-esteem.

A Framework for Addressing Adolescent Problems

In attempting to meet the psychological and social needs of secondary students presenting such a wide range of problems, psychologists must utilize approaches that are as multifaceted as the problems students bring into the counseling room. Sigmon (1988) offers a convenient (but not all-encompassing) framework for understanding the severity of adolescent problems and planning for a continuum of services. He proposes a five-level framework to guide school psychologists in deciding when, and how intensely, to counsel public school students. His scheme provides an organization for both practitioners and program planners.

- A *Level I* student is considered to be "normally" adjusted with occasional mild problems requiring a counselor's attention, for example, academic or career choices. Other than perhaps needing someone to lend an ear to his or her concerns, this student is not likely to need any formal psychological intervention.
- At *Level II*, a student may experience academic, personal, or behavioral problems that are situational, intermittent, and only mildly problematic. A school psychologist may offer counseling or classroom behavioral intervention when situations arise but would not typically consider this student for special education due to emotional or behavioral factors.
- At *Level III*, students experience mild to moderate psychosocial problems and are most likely to be referred for counseling intervention. These students are generally not self-destructive or severely pathological but instead exhibit behaviors that may be considered oppositional or defiant. Typical interventions might include group training in social skills, problem solving, or anger control.
- *Level IV* students present moderate to severe psychological problems that have persisted for a relatively long period. They may experience hallucinations, delusions, or exaggerated phobias and may be better served by community agencies that provide long-term therapy or medical attention, if necessary. In addition to identifying and monitoring Level IV students, school psychologists may coordinate outreach and referral programs for students requiring community or private treatment.
- *Level V* is characterized as a severe or "crisis situation" in which the student has been traumatized or shown to have been injurious to self and/or others. For example, adolescents traumatized by rape, the death of a friend or family member, courtship or community violence, or substance abuse may require specialized and immediate attention from not only school counseling services but external services as well (e.g., rape/abuse crisis center, psychiatric emergency room, medical or psychiatric hospital, or substance abuse treatment program).

To meet the wide range of psychological challenges faced by today's secondary students, schools must be prepared to provide counseling services across all of Sigmon's five levels.

BEST PRACTICES IN COUNSELING PROGRAM DEVELOPMENT

Counseling programs may be described in many ways. Kruger (1988) defines a *program* as "a system of staff, materials, and procedures intended to improve or resolve a problem that a group of students have in common" (p. 491). Schmidt (1993) more explicitly characterizes the comprehensive counseling program as providing "individual and group counseling, consulting, testing and assessment, group instruction, and referrals" and serving students, parents, and teachers "within the framework of an organized program" (pp. 31–32).

Psychologists need to think on the developmental program level so that the overall mental health and counseling needs of the school are not misunderstood or slighted in favor of reactive, case-by-case response. Psychologists must be more systematic in both identification and intervention, rather than allowing counseling activities to be governed by the interests of individual counselors or the transient, albeit serious, concerns of highly vocal groups of students, parents, or teachers. Instead, the needs of the entire school community must be considered when developing and allocating resources.

ESTABLISHING A COUNSELING PROGRAM: PROCEDURES IN PROGRAM DEVELOPMENT AND CHANGE

Professional conferences and catalogues abound with descriptions of predesigned educational programs, including those addressing the mental health needs of students. Kruger (1988) offers some sound advice for those considering such programs in their own schools. "Programs described in journals or books should not be merely adopted 'as is' by a school. All schools in their overall contexts are unique, and sometimes the variations make a difference in how change should occur" (Kruger, 1988, p. 491). It is unlikely that many psychologists will actually be involved in *establishing* a school counseling program from scratch. More likely is the psychologist's participation in program *modification* at the building and/or system level.

Reflecting a systems orientation, Schmidt (1993) presented a model for counseling program development, involving four basic phases: (a) planning, (b) organizing, (c) implementing, and (d) evaluating. Rather than functioning as sequential steps, these phases operate in a cyclical fashion, with each step feeding the next in an ongoing, developing system. For example, rather than serving as the final phase of a program, evaluation leads to planning of new or revised programs, and the cycle continues. Psychologists may wish to examine current practices in their own settings to determine in which phases their skills might best be utilized and how best to accommodate the unique needs and life challenges of adolescents in their own schools.

Program Planning

Program planning involves identifying and clarifying the problem(s); evaluating school-wide goals; and assessing the needs of students, staff, and parents. Illback, Zins, Maher, and Greenberg (1990) refer to the activities in this phase as "problem clarification," designed to "gather systematic information to place the problem(s) in context and to assure that the appropriate planning occurs based on a clear understanding of service needs" (p. 807). This requires two separate but compatible strategies: (a) initial contextual analysis and (b) formal needs assessment.

Contextual analysis. Using a variety of strategies, contextual analysis involves placing the problem "in context."

> Through preliminary interviews with involved persons, records reviews, direct observation, and similar methods, [the program planner] seeks ... to obtain a general sense of the history and development of the concern, to understand what the present state of affairs appears to be, to know which individuals perceive that there is a problem, and to recognize there are multiple perspectives from which the problem may be viewed. (Illback et al., 1990, p. 807).

Whether engaged in initial program development or program modification, psychologists and other professionals involved in the process must understand the setting before deciding how (or whether) to proceed. It is crucial to assess, for example, whether change is needed, which characteristics of the setting and staff support and hinder change, and how a school might become more amenable to change (see Kruger, 1988, for further discussion). Answers to such questions can provide a clear understanding of the context and serve as a guide in the next step, formal needs assessment.

Needs assessment. In school settings, needs assessment for counseling frequently consists solely of surveys administered to students or teachers addressing the need or desire for specific types of services, for example, grief support groups following the death of a classmate. But, many other strategies are available for gathering multisource data that will inform the development of the overall program. Indeed, in a comprehensive counseling program, needs must be assessed across all four approaches to service — crisis, remedial, preventive, and developmental. Although the variety of needs assessment strategies cannot be discussed in detail here, Illback et al. (1990) suggest several which can be applied at the planning stage (see Table 2). Data collection from multiple sources (e.g., students, teachers, parents, administrators, existing documents) will then serve as the basis for clarifying the problem, defining the need(s), and negotiating with decision makers about competing needs and priorities. This process leads to setting relevant goals and objectives and designing an overall program structure to address the identified needs and problems.

Program Organization and Development

The program organization phase may be considered an extension of the planning stage, in which the focus shifts to identifying and developing the appropriate services and resources to support the program structure. Resources include personnel, participants, activities, skills, materials, space, and time. Basically, the task is to determine *who* will do *what* with *whom, when.* In making these determinations, planners must consider the various approaches (i.e., crisis, remedial, preventive, and developmental) included in the counseling program.

Even when readily available, resources may still require organization to coordinate them into the overall program, or policies outlining their usage may need to be written. When resources are not yet available, it may be necessary to hire or train staff, develop or purchase materials, and establish the timelines necessary to accomplish these tasks. In this phase, areas of responsibility are designated.

The skills required to conduct effective counseling are frequently overlooked as essential program resources. When assigning and training staff, however, their mastery of requisite knowledge and skills should receive primary consideration. The professional literature provides some guidance for hiring and training counseling staff suggesting that, to promote growth and change, psychologists should possess certain generic characteristics. For example, effective counselors are authentic, empathic, and warm in their interactions with clients. In addition, they serve as role models, display genuine concern, and instill hope that clients can and will change (Corey, 1986; Ivey, Ivey, & Simek-Downing, 1987). While not comprehensive in scope, these characteristics do provide a foundation from which to offer effective psychological services.

Although generic counseling knowledge and skills are essential, they are not sufficient for establishing and maintaining effective therapeutic relationships. To meet the psychological needs of students confronted with unique social challenges, counselors must be prepared to work with students whose life experiences may be different from their own. Accordingly, Sue et al. (1982) maintain that the professional repertoire of culturally competent counselors must include various fundamental beliefs/attitudes, knowledge, and skills (see Table 3). Although their model was aimed primarily at clinicians working specifically with ethnically diverse clients, similar characteristics may apply to those counseling students who are in any way different from the mainstream. Experience, expertise, sensitivity, and flexibility in a wide range of counseling skills should be considered in assessing available and needed resources, both in terms of personnel and training needs. However, rarely do all essential resources exist within the confines of the school building. Pro-

TABLE 2
Needs Assessment Strategies

Strategy	Description
Key informant approach	Interview those in central positions ("experts") in the organization who have knowledge about the problem
Indicators analysis	Use school's (and other organizations') existing data bases relevant to the problem
Analysis of demands for services and analysis of service resources	Use data and records that are already available, for example, number of individual counseling appointments, number of students on waiting lists
Survey/Questionnaire	Ask a sample of respondents about the problem, for example, particular counseling needs
Nominal group approach	Involve representatives of the various constituencies in group discussion and analysis of the problem
Delphi approach	Involve experts in systematic series of questionnaires
Community forums	Conduct open discussions of interested parties

Note. Based on Illback, R. J., Zins, J. E., Maher, C. A., & Greenberg, R. (1990). An overview of principles and procedures of program planning and evaluation. In T. B. Gutkin & C. R. Reynolds (Eds.), *The handbook of school psychology* (2nd ed.; pp. 799–820). New York: Wiley.

gram planners may also consider community agencies such as mental health centers, recreational programs, substance abuse treatment services, and university training programs as resources to be tapped. In some locales, partnerships have developed among schools, universities, and/or community organizations, resulting in services such as school-based clinics and social service programs (see, e.g., Godin, Jacobs, & Nowak, 1993; and the School Mental Health Project, Institute for Families in Society, University of South Carolina) and crisis teams invited into school settings on an as-needed basis to assist school-based teams (e.g., Boston Public Schools' collaboration with the multi-agency Community Crisis Response team of Cambridge Hospital).

Program Implementation

Schmidt (1993) described program implementation as the "action phase," in which services are delivered as designed. To those who prefer jumping into the cycle at this stage, without careful prior planning and organizing, Schmidt offers the following caution:

> Implementing a program that is void of clear goals and objectives is like piloting a plane without a flight plan. The plane is airborne, all instruments are working, but the pilot has no idea where the plane is heading or why it is going in that direction. (1993, p. 43)

And, it is likely that the pilot will not know when the plane has arrived.

Maher and Bennett (1984) proposed a model of program development which stresses ongoing interaction among program planners, staff, and participants. Of particular relevance to the implementation phase, they highlight rewarding and adapting as important activities in fostering program success. Rewarding is not often cited in discussions of program development but may deserve special attention at the secondary level. While true in any setting, it may be in the high school, with its reliance on frequent class changes throughout the day, that the cooperation of teaching staff is most essential to service scheduling and delivery. Both written and in-person acknowledgment (Maher & Springer, 1987), as well as feedback about individual and group progress when appropriate, will contribute to ongoing, needed teacher support.

Modification and adaptation are also often needed, especially in the early stages of program implementation. For example, changes in scheduling, staffing, location, focus, or number of counseling services are not uncommon. Anticipating such changes, through ongoing discussion with administrators, staff, parents, and students, can prevent or at least reduce resistance and objections.

Program Evaluation

Frequently, program developers and practitioners are reluctant to participate in any form of evaluation, fearing that it will lead only to the dismantling of services. Cowen, however, described the value of program evaluation:

TABLE 3
Characteristics of the Culturally Competent Counselor

Areas of Competence	Description
Beliefs/Attitudes	Becomes aware of own cultural history and respects differences
	Becomes aware of own values and biases and how they may affect clients
	Comfortable with client despite racial and/or worldview differences
	Sensitive to circumstances (e.g., racial identity development) that may warrant referral to another counselor who is more culturally similar to client
Knowledge	Good understanding of the sociopolitical system's operation in the U.S. with respect to treatment of minorities
	Knowledge about client's racial/ethnic group
	Has explicit knowledge and understanding of the generic characteristics of counseling and psychotherapy
	Aware of the institutional barriers that prevent many people of color from using mental health services
Skills	Able to generate a wide variety of verbal and nonverbal responses
	Able to send and receive verbal and nonverbal messages accurately and appropriately
	Able to exercise institutional intervention skills on behalf of client when appropriate

Note. Based on "Position paper: Cross-cultural counseling competencies" by D. W. Sue, J. E. Bernier, A. Curran, L. Feinberg, P. Pedersen, E. J. Smith, & E. Vasquez-Nuttal, 1982, *Counseling Psychologist, 10,* 45–52.

> If a program is not evaluated at all or is evaluated improperly, the major benefits to be derived from a carefully conceptualized and conducted program — indeed one with important positive outcomes — may be lost, and the program may incorrectly be dismissed as a failure. (1984, p. 489)

From this perspective, evaluation is considered an opportunity to demonstrate a program's effectiveness, rather than the first step toward its demise. Approaches to evaluation generally fall into two categories: (a) the process of implementation and (b) the assessment of outcome effectiveness (Illback et al., 1990).

Implementation evaluation. Before the effectiveness of a given program or intervention can be assessed, it must be demonstrated that the program has actually been implemented as originally planned or as intentionally revised. Otherwise, it may be some "other" program that is actually evaluated. This issue has been discussed elsewhere in terms of treatment or program integrity (see, e.g., Kazdin & Wilson, 1978). Unfortunately, many school programs fail to conduct a systematic assessment of the integrity of implementation. But such evaluation is crucial to program development in that it "increases confidence in the eventual assessment of program outcomes by ensuring that measured effects are attributable to an intervention that has been implemented as planned" (Illback et al., 1990).

In documenting implementation integrity, many issues should be considered, including the extent to which staff are carrying out planned program activities; the extent to which students and staff actually participate; the comparison of planned and actual costs; the development of written materials; and the perceptions of various constituencies or stakeholders regarding intended and unintended effects of the program (see e.g., Bennett, 1988; Illback et al., 1990). As with needs assessment, a multimethod approach is recommended at this stage. Interviews, paper-and-pencil measures, record reviews, and observations are frequently used (Bennett, 1988; Illback et al., 1990). Once questions about implementation have been answered, the focus of evaluation may shift to program effectiveness or outcome.

Outcome assessment. As already suggested, evaluation should not be conducted only as the final stage of program development, for the sole purpose of reporting the level of effectiveness (summative evaluation). It should also be conducted as a continuous process aimed at identifying and improving services and effective methods of service delivery (formative evaluation; Stake, 1991). Whether summative or formative in purpose and timing, evaluation may assess a variety of outcomes and serve a range of purposes.

In program evaluation, effectiveness does not have a single definition. Instead, program effectiveness is determined from the perspectives of the various stakeholders who, in the model described here, have also been involved in the development and implementation of the counseling program. Thus, multiple (and sometimes conflicting) definitions and measures of effectiveness may be operating simultaneously.

Based on Bennett's (1988) definitions of "outcome" and Illback et al.'s (1990) discussion of levels of decision making, a series of questions will serve to illustrate the various perspectives from which a program's outcome or value might be assessed:

1. Have the program goals been achieved? Have the identified unmet needs been satisfied? To what extent can the level of change be attributed to the program, rather than to some other event or resource?

2. Has the program generated any unintended "related effects," whether harmful or beneficial?

3. How do the various consumers (e.g., students, parents, staff, funding sources, service providers) rate the program's effectiveness? To what extent has the program met relevant government regulations?

4. How cost effective is the program? What other appropriate cost analyses (e.g., cost-benefit, cost-utility, cost feasibility) have been conducted?

Clearly no one evaluation procedure will address the different perspectives represented in these questions. In some cases, predetermined, standardized clinical measures may provide the most useful information. Others, such as unintended outcomes, may emerge from ongoing interviews, observations, self-report measures, or record reviews. Measures of satisfaction may be collected from all participants, a random sample, or only key informants. Evaluation designs may range from true experiments to quasi-experiments to intensive case studies (see Rossi & Freeman, 1985, for a more thorough discussion of evaluation design).

As expressed by Stake (1991), comprehensive program evaluations use a variety of data collection methods to determine the level of effectiveness as well as to illuminate program areas that need improvement. As is true with any school program, strategies for performing ongoing evaluation should be developed and implemented as an integral part of a comprehensive counseling program. As such, evaluation procedures are not used simply to appease decision makers or satisfy the public during "critical" times. Rather, evaluating should be viewed as an essential (and iterative) step in the process of designing, developing, and delivering counseling services to the school community.

SUMMARY

School psychologists serve in a broad range of direct and indirect service delivery roles in secondary schools. The unique psychosocial challenges faced by today's adolescents, however, call for expanding the responsibilities of school psychologists to include increased time for counseling students and greater attention to developing counseling programs. These efforts demand collaboration by all teaching, administrative, and mental health staff in order to capitalize upon their collective competencies, thereby more effectively addressing the needs of all members of the school community.

A comprehensive counseling program is designed to address the crisis, remedial, prevention, and developmental needs of students, parents, and staff. Developing such a program requires sufficient time, skill, and commitment to interdisciplinary collaboration. The extent to which a counseling program is successful depends largely on the questions and issues addressed in the planning and organizing phases, the quality and range of resources made available during implementation, and the rigor and commitment with which ongoing evaluation is conducted.

School psychologists, in their roles as counselors and program developers, are in an ideal position to apply their assessment, intervention, and consultation skills at the secondary level. Today's youth can benefit greatly from the services of well-trained and experienced school psychologists, working collaboratively with other school and community professionals to provide high quality counseling programs.

ACKNOWLEDGMENTS

The authors would like to thank Ronald E. Reeve and an anonymous reviewer for their helpful comments on earlier drafts of this chapter.

Support was provided, in part, for work on this chapter through a postdoctoral fellowship pursuant to a National Research Service Award from NIMH (Grant #5T32MH16156) to the University of Nebraska–Lincoln while the first author was a postdoctoral research fellow with the Center on Children, Families, and the Law.

ANNOTATED BIBLIOGRAPHY

Colten, M. E., & Gore, S. (Eds.). (1991). *Adolescent stress: Causes and consequences.* New York: Aldine deGruyter.
The editors of this book bring together a series of well-written papers that illustrate the complex and multifaceted nature of adolescent stress and its implications for mental health and well-being. Topics include coping with contemporary stressors, stress as it relates to adolescents of diverse backgrounds, stress among adolescent females, adolescent–parent conflict, psychoactive substance abuse, and teenage pregnancy.

Ehly, S., & Dustin, R. (1989). *Individual and group counseling in schools.* New York: Guilford Press.
An ideal introduction for school psychologists new to counseling, this book reveals the elements of providing effective service to students at all age levels. A discussion of various theoretical orientations is provided to address students' concerns at either an individual or group counseling level. Program evaluation procedures are described, providing a comprehensive package of effective counseling service.

Kruger, L. J. (1988). Programmatic change strategies at the building level. In J. L. Graden, J. E. Zins, & M. J. Curtis (Eds.), *Alternative educational delivery systems: Enhancing instruction options for all students* (pp. 491–511). Washington, DC: National Association of School Psychologists.
This helpful chapter provides school psychologists detailed information in the development and implementation of any school-based program. In addition to presenting strong arguments for programmatic change at the building level, Kruger thoroughly describes the tacit knowledge (i.e., personal attitude, school culture, professional literature, planning skills, and interpersonal influence skills) needed by school psychologists before initiating change at the building level.

Meeks, J. E., & Bernet, W. (1990). *The fragile alliance: An orientation to the psychiatric treatment of the adolescent* (4th ed.). Malabar, FL: Krieger Publishing.
A classic in the field of adolescent psychotherapy, the most recent edition of this text, targeted at experienced clinicians, has expanded its focus on the real-world problems faced by contemporary high school students. In addition to basic clinical considerations in adolescent treatment, special topics include suicidal threat and behavior, runaways, violence, victimization, divorce, substance abuse, and medical problems. This book is highly recommended for any practitioner specializing in adolescent treatment.

Ramirez, M. (1991). *Psychotherapy and counseling with minorities: A cognitive approach to individual and cultural differences.* New York: Pergamon Press.
Ramirez challenges the mainstream therapeutic methods counselors and psychotherapists have used when working with people of color as perpetuating the "assimilationist" perspective. Instead, he offers a model of psychotherapy and counseling based on a multicultural perspective. Ramirez's use of case histories helps characterize the primary objectives of his multicultural treatment model.

Shadish, W., Jr., Cook, T. D., & Leviton, L. C. (1991). *Foundations of program evaluation: Theories and practice.* Newbury Park, CA: Sage Publications.
Shadish, Cook, and Leviton have collected a variety of chapters written by major contributors to the field of program evaluation. Although primarily theory driven, this book provides its readers an invaluable source of evaluation information that can be readily applied to any program.

Sue, D. W. (1988). *Counseling the culturally different.* New York: John Wiley Publishers.
This book is among the classic works in the cross-cultural counseling arena. It adds meaning to related issues of counseling all historically oppressed groups, identifies differences and similarities across racial/ethnic groups in relation to counseling practices, and perhaps most importantly, addresses our social-political system's impact on cross-cultural counseling delivery services. "Critical incidents" highlight and illustrate issues and concerns that are likely to arise in typical counseling situations.

Best Practices in Teaching Study Skills

Virginia Smith Harvey
University of Massachusetts Boston

OVERVIEW

Of the many factors that influence learning (family, socioeconomic class, innate intelligence, motivation, self-image, study skills), study skills are most easily changed, and they can be taught to students of all ages and levels of ability. Thus, assessing and improving a student's study skills can be one of the school psychologists's most effective interventions.

Study skills are defined as competence in acquiring, recording, organizing, synthesizing, remembering, and using information and ideas. They are frequently broken down into skills of organization, listening, reading, writing, research, and test taking. Although many of these skills are taught throughout the regular curriculum, often instruction in study skills is neglected because we assume that students learn these skills on their own, or that they have mastered them in an earlier grade (Devine, 1987). When students are not specifically, and repeatedly, taught these skills, a large proportion of referrals to school psychologists may be students whose study skills are not well developed. Often interventions to improve organization or study skills can take place in the prereferral stage and prevent the need for more extensive assessments and interventions.

This chapter provides a framework for understanding study skills, assessment methods, and intervention strategies. The intervention techniques presented here are a small sample of effective interventions. Many additional intervention techniques, as well as resources for classroom interventions, are cited in the references (Graham & Robinson, 1989; Langan, 1978; Mannix, 1989; Segal, Chipman, & Glasser, 1985).

School psychologists' training greatly facilitates their work in assessing and improving students' study skills. Integral to work in this area is knowledge of human learning and memory, skill in assessing individual differences, knowledge of learning styles, skill in consulting with parents and teachers, and expertise in ecological assessment.

BASIC CONSIDERATIONS

Study skills are taught best in conjunction with regular coursework and homework. If taught in isolation, they are unlikely to be maintained or to transfer from one setting to another. Therefore, effective remediation requires that the school psychologist, teacher, and parent work closely together to determine appropriate procedures, designate responsibilities, and design techniques to encourage generalization to other tasks.

BEST PRACTICES

The school psychologist should assess study skills particularly when the referral question concerns academic effort or behavior. Referral questions that suggest deficiencies in study skills include "does not complete assignments," "doesn't complete homework," "doesn't follow directions," and "isn't organized." Poor grades in social studies and science, and poorer performance on tests than in discussions, also suggest poor study skills.

If the same referral questions arise repeatedly, one should investigate the adequacy of the teacher's and/or school's instruction in study skills. Often students are taught these skills only once, with the assumption that they will then practice the techniques independently. Actually, these skills must be reviewed every year, and often require ongoing monitoring.

Home-School Collaboration

Given that most studying takes place at home, home-school collaboration is imperative. Teachers, for example, need to communicate with parents about problems with homework. Similarly, parents need to help with homework and organization. Parents also should let the teacher know when excessive time is being spent on homework, so that the load can be reduced. Parents will find extremely helpful suggestions in *Homework Without Tears* (Canter & Canter, 1987) and *How to Help Your Child Achieve in School* (1988). In addition, this volume contains a chapter on improving home-school collaboration, to which the reader is referred.

Assessment of Existing Study Skills

Loene (1983) indicated the following steps when teaching study skills:

1. Conduct an assessment and define the area to be taught.

2. Determine the entire procedure, including assessment, monitoring, and reinforcement.

3. Teach the techniques.

4. Gradually increase the student's responsibility.

5. Practice for transfer to other classrooms and subjects.

6. Provide regular feedback.

7. Use alternative technique if setbacks occur.

8. Evaluate the process before termination.

Some formal instruments for assessing study skills exist (Brown & Holtzman, 1967; Demos, 1976). However, the most productive method uses the ecological approach of investigating in several domains and at several levels. The following steps should be taken:

1. Interview the teacher and parent during a prereferral conference, using the Study Skills Assessment Checklist (Table 1) to determine general areas of weakness. During the interview most of the questions will be answered and the areas of significant deficiency should be apparent.

2. Observe the student in class and analyze work samples to obtain further information. Selectively use the Checklist of Classroom Qualities that Foster Study Skills (Table 2) during the observation.

3. Interview the student. Selectively use questions from the Study Skills Assessment Checklist and the Student Interview Questions (Table 3). Have the student complete work with you. While the student works, observe carefully and have the student describe his or her work method. Examine the student's notebooks, assignment books, and completed work. Have the student show and describe his textbook. Have the student write down his or her weekly schedule, or keep a log of activities for a week, to help determine when homework "fits in."

4. Determine appropriate intervention techniques. The remainder of this chapter expands on the Study Skills Assessment Checklist. Often the remedial step to be taken will be readily apparent, but some suggestions are supplied and many more can be found in the references. Instruction can be provided at the individual, small-group, or classroom level. Several commercial materials are available as curriculum guides, some of which are listed in Table 4. Other possible intervention approaches include teacher consultation, teacher training, and/or district curriculum consultation. As mentioned previously, teachers often assume that students already have acquired many of these skills in earlier grades. The school psychologist is in a good position to observe the extent of the need for study skills training and to consult with teachers and administrators in that area.

5. Develop a plan of maintenance and generalization for the interventions. The implementation of almost all interventions will require ongoing monitoring until they become habitual on the part of the student.

Basic Skills in School

Does the student understand that he or she has some control over his or her life and academic achievement? Students whose locus of control is completely external will need to be led through successful experiences to help them understand that the effort they expend relates to the outcome they experience, and that their success in school is not simply an effect of innate ability or luck. One method of linking personal success to effort can be to ask students "when" questions, such as "How old do you think you will be when you learn to read?" Another is to have each student keep a log of activities for a week to track time spent on tasks and resultant success level.

Are assignments turned in with a label, name, and date? Are they neat? Are they complete? Are assignments checked for errors, and corrected, before being turned in? Students need to develop the habit of checking their work before turning it in. One method is for the teacher to give the entire class time to check over their work before collecting it, and then fade active monitoring. On the individual level, papers can be turned back to the student (nonpunitively) when it is immediately apparent that checking is needed. The acronym COPS can be used to remind to check for Capitalization, Overall appearance, Punctuation, and Spelling (Wiens, 1983).

Are all materials necessary for homework completion brought home? "Forgetfulness" can be alleviated by home-school collaboration. At school, the teacher can remind students to check that they have their homework and necessary materials before the dismissal bell. At home, parents can implement a simple behavior-management system to reinforce bringing materials home. One effective technique is to require the student to spend time on academic activity even when homework was forgotten. Other parents solve the problem by having the child walk back to school to get forgotten materials, or by charging "gas money" for return trips to a distant school.

TABLE 1
Study Skills Assessment Checklist

Basic Skills in School

Does the student understand that he or she has some control over achievement?

Are assignments turned in with a label, name, and date, neat, complete, checked for errors, and corrected, before being turned in?

Are all materials necessary for homework completion brought home?

Are short-term assignments tracked in a book; long-term in a calendar?

Does the student (grades 4 and below) keep a folder for assignment sheets?

Does the student (grades 5 and agove) keep a loose-leaf notebook organized chronologically, by subject?

Does the teacher come to class with notebook, pencil, completed homework, books?

Is the student's desk, cubby, or locker neat?

Can the student use the catalogue in the library?

Can the student use the periodical index?

Basic Skills at Home

Where does the student prefer to do homework? Is there a place at home to study that is quiet and well lighted, with a table or desk? Are supplies, reference books, and a dictionary kept there?

Is there a regular, quiet time to study at home?

Does the student estimate how long it will take to complete an assignment? Is this estimate used to make a schedule? Is the schedule followed?

Does the student follow a schedule?

What does the student do when unable to understand something at home?

What kind of homework does the student enjoy? Dislike? Why?

What does the student like about the way he or she handles homework? Dislike?

Does the parent regularly check the assignment calendar/homework sheet?

Listening Skills

Are directions understood?

Are directions followed?

Does the student listen in class?

Are notes taken in class?

Are details added to class notes as soon as possible after class?

Is a note-taking system used?

Are abbreviations and symbols used while taking notes?

Is particular attention paid to important items cued by the lecture?

Are relevant reading materials preread before the lecture on the material?

Reading Study Skills

Is the purpose of reading the material understood?

Does the student preread?

When there are words taht the student doesn't understand in the reading, does the student detemine their meaning and write them down?

Is the student easily distracted or bored while reading?

Does the student know how to take notes in textbooks?

Is the student able to adjust reading speed to the material?

Is a reading technique used when reading difficult assignments?

Does the student outline reading assignments? Does the student know how to "map" a reading?

Does the student use headings and other typographical aids?

Can the student read tables, charts, and graphs?

Does the student know how to use the table of contents and index of a book?

(... Table 1, continued)

Is the student able to comprehend the textbooks?

Can the student predict outcomes, distinguish fact from opinion, discern emotional appeals, recognize bias, discern inference?

Reporting Skills

Does the student organize thoughts before beginning a written assignment? Does he or she write a first draft?

Does the student proofread for success/failure in answering the purpose of the assignment, legibility, neatness, spelling, complete sentences, and punctuation errors?

With which reporting techniques is the student most familiar? Most capable?

Which does he or she prefer?

Test-taking Habits

Does the student space learning over several sessions (vs. cramming)?

Does the student study using the SQ3R (see Reading Study Skills) or a similar method? Does the student use study guides while studying?

Does the student predict test questions?

Does the student know and use good test-taking strategies?

Does the student perform significantly better on practice than on actual tests?

Are short-term assignments kept track of in a book or log? Are long-term assignments, tests, reports, and projects kept track of in a calendar? Assignment books or sheets and calendars should be required of all students as soon as they are expected to complete work independently. Often teachers need to make sure that assignments are actually written down, and school psychologists often need to reinforce teachers for monitoring this procedure. If a student has considerable difficulty writing down assignments, even given careful monitoring by the teacher, a "buddy" can be seated next to the child to help make sure assignments are recorded.

Students need specific guidance in learning how to break long-term assignments into small components and integrate the components into their assignment books. The use of a calendar becomes critical as students become older and have multiple long-term assignments as well as multiple teachers.

Does the student (grades 4 and below) keep one folder for assignment sheets with "work to do" on the left and "work to turn in" on the right? This is an extremely effective method for managing work sheets in the lower grades. Often children at this age level find "Trapper-keepers" and notebooks too cumbersome and confusing.

Does the student (grades 5 and above) keep a loose-leaf notebook organized chronologically, by subject? Loose-leaf notebooks are most efficient because handouts and notes from the textbook can be added in chronological order. Each subject should be in a separate section. There should also be a pouch for supplies and a section for assignments.

Does the student come to class with notebook, pencil, completed homework, and textbook? Students need a certain place at home to keep materials "to go to school." It is important that this place not be cluttered with other materials. If a student does come to class unprepared, less desirable supplies should be given as substitutes to avoid reinforcing irresponsibility.

Is the student's desk, cubby, or locker neat enough that the student can locate required materials quickly? Teachers can provide specific times for the entire class to clean out both desks and notebooks. Students with severe organizational problems will need an adult or mature student buddy to help sort their papers. Unscheduled and scheduled notebook and desk checks, with rewards for good organization, are helpful. For students who become disorganized between classroom cleanups (for some students this can be daily), a cleaning routine should be established, with neatness criteria, timeline, and reinforcement for keeping neat enough so that major cleanups are not necessary.

Can the student use the catalogue in the library? Can the student use the periodical index? Surprisingly large numbers of older students are not independent in using these essential resources.

Basic Skills at Home

Where does the student prefer to do homework? Is there a place at home to study that is quiet and well lighted, with a table or desk? Are supplies, reference books, and a dictionary kept there? Where a

TABLE 2
Checklist of Classroom Qualities that Foster Study Skills

General:	The class climate is positive
	The teacher relates the material to students' experiences.
	Tasks are stimulating and challenging.
	Students are treated as individuals with varied needs and talents.
	Regular successes are experienced by the students, and displayed.
	The classroom is organized.
	The classroom is free from unnecessary distractions: quiet for independent work, with minimal visual distractions.
	Expectations for students are clear.
	Students are allowed to help set goals and choose reinforcers.
	Students are not subjected to public humiliation.
	Advance organizers are provided.
	Before speaking, the teacher gains the attention of the class.
Assignments:	Students are given prompt feedback.
	Work is collected, corrected, and returned promptly.
	The teacher gives assignments both orally and in writing.
	Assignments are clear.
	The teacher checks that students write assignments in an assignment book or long-term calendar when assigned.
	Homework assignments follow successful classroom practice.
	Worksheets have sufficient writing space (e.g., second grade arithmetic is not typewritten), are dark enough to read.
	Writing assignments are integrated into the curriculum.
Lectures:	Unfamiliar concepts are taught before lectures or readings.
	Students are taught to relate material to their own lives.
	Frequent examples are given in class.
	Visual aids are frequently used.
	Relevant material is distinguished from irrelevant material.
	The teacher frequently checks for students' understanding by asking open-ended questions related to the topic.
	When children do not understand, the teacher rephrases, substituting key words and simplifying grammar.
Reading and notetaking:	Students are taught to recognize a speaker's or writer's purpose.
	Students are taught to identify their own purposes in reading.
	Students are taught to note transitions in the talk or text.
	Students are taught to recognize main points.
	Students are taught to note supporting details and examples.
	Students are taught to note the sequence of ideas.
	Students are taught to take notes.
	Students are taught how to summarize.
	Students are taught how to draw conclusions.
	Students are taught how to make inferences.
Tests:	Tests are administered in a low-anxiety atmosphere.
	Students know test question formats before the test.
	The material to be covered on tests is clear to students.

TABLE 3
Student Interview Questions

About you:	What do you like to do best?
	What do you like to do least?
	What do you do especially well?
	What do you least well?
	What do you get praised for doing?
	What are your strongest skills and abilities?
	What are five jobs you might like to have as an adult?
	What would you like to know, and know how to do, when you have finished school?
At school:	What are your favorite school activities?
	What do you dislike most about school?
	Why do you think you don't do well in school?
	What are five skills you believe are important to succeed in school?
	What grades do you want to get in school?
At home:	What grades do your parents want you to get in school?
	Do your parents praise you for your school work?
	Where do you like to study? When?
	How much sleep do you get each night?
	What type of exercise do you get? How often?
	What chores do you have at home?
	Keep a log of your activities for a week, blocked off in half-hour units.

student prefers to study needs to be taken into account. Some students find working in their own room too lonely, and constantly seek adult attention to alleviate loneliness. Such students may study better at the kitchen table while supper is prepared. Other students may prefer to work at the library, and transportation will need to be negotiated. The most effective strategy is for a student to study in only one place, so that efficient studying is associated with that location.

Is there a regular, quiet time to study at home? Helping parents and students agree upon a "study hour" is one of the simplest yet most effective interventions. Finding a quiet time to study can be very challenging in busy households, and the establishment of a daily study hour best takes into account already scheduled extracurricular activities, chores, and favorite TV shows. In addition to these factors, the student's ability to concentrate at different times of the day should be considered. Some can focus much better in the early morning, others after supper, and others right after school. Many elementary school children are too tired after dinner to be able to concentrate efficiently, and this is demonstrated by their being easily frustrated and slow to complete tasks. Ideally, the family agrees upon a study hour (perhaps 7:00 to 8:00 each night), the television and stereo are turned off, phone calls are not taken, and the entire family studies, reads, or completes paperwork.

Does the student estimate how long it will take to complete an assignment? Is this time estimate used to make a daily schedule? Is the schedule followed? Students often have unrealistic ideas of the length of time it takes to complete given tasks. Timing a student completing a worksheet or reading assignment can produce helpful planning guidelines. Daily schedules should be written down. If keeping to the schedule becomes problematic, a behavior management system can be implemented.

Does the student follow a schedule and do the same things at about the same time every day or week? A routine schedule, although difficult to achieve in many busy families, has many advantages. Most important, a routine reduces arguments between parents and students.

What does the student do when unable to understand something at home? Some parents are clearly more skilled at helping with homework than others, and some students have no one whom they feel comfortable asking for help. If this is the case, students will need help brainstorming how they might solve this dilemma. Sometimes a neighbor or another family member (older sibling, cousin, grandparent) can be helpful; some communities have a homework hotline; some students prefer to ask the teacher for help before or after school. Often it is helpful for students to have "study buddies," peers who have shared their telephone numbers and call one another for help.

What kind of homework does the student enjoy? Dislike? Why? Asking students what kind of homework they like is interesting because most students assume they dislike all types of homework, when they actually do have homework they like (projects, perhaps). Knowing homework preferences helps in developing a homework schedule. Some students prefer to get the disliked homework done first, while others prefer to do their easier work first. Students can be made aware that when they dislike a subject, they can find ways to make it less frustrating. For example, they might set themselves a goal of doing five math problems and then taking a stretch.

What does the student like about the way he handles homework? Dislike? Whatever students dislike about the way they handle homework can be subjected to a brainstorming session. Then one of the solutions brainstormed can be chosen, tried, and evaluated. For example, a student may dislike a habit of procrastinating, and may decide to try rewarding himself with a telephone call to a friend or shooting baskets after completing an assignment.

Does the parent regularly check the assignment calendar/homework sheet with the child, as well as checking for notices, permission slips, and other school communication? Does the parent monitor homework completion? Students generally need help from their parents in prioritizing activities, establishing consistent homework and bedtime routines, and organizing books, notebooks, and papers for return to school. Even more important, they need their parents to provide structure and praise. Generally, students need less supervision as they get older, and by junior high they often make and keep their own homework schedule. Some adolescents, particularly students with LD, will continue to need considerable parental involvement.

Listening Skills

Are directions understood? The comprehension of oral communications is often assumed, yet students frequently do not understand what is said to them. Comprehension of directions can be checked by having students tell you, in their own words, what needs to be done. It is helpful for students to write (circle, if the directions are written) each action word, number each action, and cross off each number after completion (Kuepper, 1990).

Are directions followed? If students understand the directions yet still do not follow them, perhaps they do not attend to directions, or they do not want to follow directions. The former can be remedied by having the student read the directions subvocally before starting the paper. Lack of desire to follow directions needs to be further explored in an expanded student interview to determine the benefits (such as adult attention) the student gains from noncompliance, and to delineate alternate methods to obtain the same benefit.

Does the student listen in class? Not listening in class can be caused by many factors, including chronic or intermittent hearing loss, preoccupation with personal issues, a boring presentation, or weak listening skills. Many studies have demonstrated that listening skills can be taught (Devine, 1987); a number of strategies to improve listening skills are provided by Devine (1987) and Williams et al. (1993).

Listening skills can be assessed through the use of standardized instruments, including the Woodcock-Johnson Psychoeducational Battery (Woodcock & Johnson, 1989). The Test of Language Competence (Wiig & Secord, 1989) assesses the knowledge a student has of the deep meaning of language, including idioms, making inferences, and understanding dual meanings. The Clinical Evaluation of Language Fundamentals-Revised (Semel, Wiig, & Secord, 1989) assesses comprehension of oral directives, sentence structure, linguistic concepts, and oral paragraphs. If one determines that the student has a deficiency in one of these areas, efforts toward remediation and compensation will be appropriate.

Are notes taken in class? Does each page of notes have the date and topic written at the top? Notetaking has several advantages, including improving acquisition of material and improving the ability of students to listen. Students' ability to take orderly notes needs to be assessed by every teacher, and students often need supervised practice. Notes should be orderly, labeled, and legible, written in the student's own words, and contain all key words and some supporting details. Many of the materials included in Table 4 have specific methods to teach these skills.

Are details added to class notes as soon as possible after class? Completing notes right after class is extremely beneficial because it provides another learning trial, and because students are better able to remember and correct details if only a short time has elapsed. It is very beneficial if the teacher allows time for this at the end of the class period, so students can ask questions about unclear material at that time.

Is a note-taking system used? Many students find it helpful to divide each page by a vertical line, taking notes on the right side and later writing "key ideas" (to be used as a study guide) on the left side.

Are abbreviations and symbols used while taking notes? Students should be encouraged to develop their own "shorthand" system.

Is particular attention paid to important items cued by the lecture? Verbal cues include repetition, foreshadowing ("We will now discuss"), consensus ("Many agree"), issues ("It's a point of debate"), absolutes ("No one," "It is certain"), summaries, and reviews. Nonverbal cues include gestures, blackboard writing, and changes in movement, tempo, and volume.

Are relevant reading materials preread before the lecture on the same material? Prereading greatly increases understanding of a lecture. It also is another method to space learning trials, and produces much better retention. It has the added advantage of encouraging the student to focus on unfamiliar words or concepts, and ask about them in class.

Reading Study Skills

Is the purpose of reading the material understood? To increase motivation and the ability to comprehend reading material, students need to understand the purpose for the material. This includes why the teacher has assigned the material and how the reading assignment relates to students' learning goals. It also includes generally understanding the author's intentions, being able to ask questions, and reading actively to answer questions.

Does the student preread? Prereading takes very little time but is one of the most important techniques to aid in understanding material. Nonfiction is preread by reviewing nontextual cues (title, author, publication date, headings and subheadings, picture, graphs, charts), reading the introduction, preface, and conclusion, and skimming the body. Fiction is preread by reading the front cover, back cover, and introduction, and skimming the first 25% of the material to determine setting, character, and plot.

When there are words that the student doesn't understand in the reading, does the student determine their meaning and write them down? SSCD (Devine, 1987) provides four approaches to unfamiliar words: Sound (students sound out the word to see if it is already in their listening vocabulary), Structure (analyze the word for familiar prefixes, suffixes, and roots), Context (guess at the meaning using clues in the surrounding passages), and Dictionary (use the dictionary or glossary to look up unfamiliar words). An alternative to using the dictionary might be asking a peer or adult.

Is the student easily distracted or bored while reading? If a student is easily bored or distracted, it can be helpful to determine how long the student can concentrate and have him or her take a brief break every so often. Taking notes, outlining, mapping, and writing down questions while reading also aid attention. Other techniques include relating something known to the topic being read, guessing what will come next, visualizing the material (making a mental movie), and making time lines or flow charts to track events while reading.

Are personal copies of textbooks available to the student? Does the student know how to take notes in textbooks by highlighting or making margin notations? Personal copies of textbooks enable students to use them as much more effective learning tools. Writing margin notes in reaction to the text is more effective than highlighting because it is more active. Only one or two sentences per paragraph should be highlighted.

Is the student able to adjust reading speed to the material? Is a reading technique used when reading difficult assignments? Effective readers vary their reading speed according to the difficulty of the material. Particular care needs to be taken with difficult assignments; several techniques enable students to better understand complex reading material. The best known, SQ3R (Robinson, 1961) has these steps:

Survey: Look over the material before beginning to read to obtain a general framework in which to store supporting details. Particular attention should be given to the title, chapter headings and subheadings, charts and pictures, the introductory paragraphs, and the conclusion.

Question: Write down questions about the material before beginning to read. These questions should reflect curiosity about the topic. Another source of questions is converting headings and subheadings into questions.

Read: Read through the material in the normal way. Add unknown words to the list of questions.

Recite and Write: Give the answers to the questions to another person, or write them down. Summarize the material in writing.

Review: Go over the material several times before being tested, attending particularly to the author's purpose and key points, until overlearning occurs.

Does the student outline reading assignments? Does the student know how to "map" a reading? Outlining is one of the most effective recording techniques. It is frequently taught in the intermediate grades, but a student's ability to outline should be checked at the secondary level as well. To "map," the main topic is placed in the middle of a blank sheet of paper. Subheadings branch from the main topic, and supporting details branch from the subheadings. This creates a highly effective visual aid that increases organization and comprehension (Sebranek, Meyer, & Kemper, 1992).

Does the student use headings and other typographical aids? Can the student read tables, charts, and graphs? Does the student know how to use the table of contents and index of a book? These abilities can be checked by having the student show the psychologist his textbook, read some of the graphs and charts, and find items using the table of contents and index.

Is the student able to comprehend the textbook? Several methods may determine a student's ability to comprehend the assigned textbook. First, it is very useful to have the student review his textbook orally, explaining the pictures, graphs, and general material in a previously studied chapter. Second, have the student read aloud a passage from the text. The student should be able to read with 90% word calling accuracy and 75% accuracy in answering comprehension questions.

A second method to assess a student's ability to comprehend content material is to devise a Cloze test. This is done by photocopying approximately 260 running words from the text. The first sentence is left complete; then one of the first five words in the second sentence is blanked out, as is every fifth word until there are fifty blanks. Finish with a complete sentence. The student then reads the passage, guessing the missing words. The student should be able to guess at least 60% of the missing words (Jacobson, 1990).

A third method is to determine the readability level of the textbook and compare this score with the score obtained on a standardized reading test, such as the Test of Comprehension of the Woodcock Reading Mastery Test-Revised (Woodcock, 1987) or the Test of Reading Comprehension (Brown, Hammill, & Wiederholt, 1986). Publishers often calculate readability through one of the several indices. The problem with this method is that the scores vary considerably and even when the score is at the student's reading level there is no guarantee that the student can actually understand the text.

Several strategies can be used when a student is unable to comprehend a text: audiocassette-taping the textbook, using high-interest low-vocabulary materials, teaching textbook structure, preteaching, providing advance organizers (which might include the teacher's notes), and teaching textbook reading strategies (Meese, 1992). Devine (1987) and Robin (1983) also suggest multiple methods of dealing with students who are unable to read content area materials.

Can the student predict outcomes, distinguish fact from opinion, discern emotional appeals, recognize bias, discern inference? If not, the student will find it difficult to understand reading material at the secondary level. These critical thinking skills typically are taught in the intermediate grades, but most students will require additional instruction throughout their schooling.

Reporting Skills

Does the student organize papers, by outlining or using a story map, before writing? Does the student write a first draft? Does the student proofread for success/failure in answering the purpose of the assignment, legibility, neatness, spelling, complete sentences, and punctuation errors? Again, these skills typically are taught in the intermediate grades, but most students will require additional instruction throughout their schooling.

With which reporting techniques is a student familiar? Most capable? Which does he or she prefer? Besides the traditional oral and written reports, nonverbal reporting techniques are available. These include preparing charts and graphs, making models, making maps, dramatic presentation, pictures, or photographs. The use of these techniques is not limited to the traditional subject: For example, maps can be employed in English class to indicate dialect use (Devine, 1987). Many students, particularly those with learning disabilities, prefer using nonverbal reporting techniques, and the school psychologist can consult with the classroom teacher to help develop appropriate nonverbal reporting techniques in various content areas.

Test-Taking Habits

Does the student space learning over several sessions (vs. cramming) and use a study plan? Does the student conduct weekly reviews? Studying for a test should be spread over several days and divided into several small units. A great deal of research has demonstrated that spaced practice results in better learning than massed practice (What works: Research about teaching and learning, 1986).

Does the student study using the SQ3R (see Reading Study Skills) or a similar method? Does the student use study guides while studying? In addition to using study guides provided by teachers and in the textbook, it is helpful for the student to group information into meaningful units. "Mapping" and other visual aids are particularly helpful to this end.

Does the student predict test questions? Having a student make up test questions while studying, including multiple choice, short answer, and essay questions, is a very effective study technique.

Does the student know and use good test-taking strategies? These include coming to the exam with everything needed; reviewing the directions carefully, including any sample items; skimming through the entire test to determine its scope; setting up and keeping a schedule; reading each question carefully (on essays, responding precisely to words such as discuss, describe, illustrate, explain, evaluate; on multiple choice, being wary of words such as always, never, everyone); outlining the important points to be covered before responding to an essay question; postponing an extremely difficult question; attempting to answer every question; writing neatly; and rechecking work before handing it in (Deese & Deese, 1979).

Does the student perform significantly better on practice tests than on actual tests? If so, anxiety may be reducing test performance; relaxation and/or slow breathing exercises may be helpful. Cognitive behavioral strategies outlined by Ottens (1984) also may be useful.

SUMMARY

Study skills significantly affect students' school functioning and can be taught at all ages and levels of ability. Teachers often do not provide instruction in study skills because they assume that students already have mastered them. Frequently diagnosis and interventions to improve organization or study skills can take place in the prereferral stage and prevent the need for more extensive assessments and interventions. School psychologists' training greatly facilitates their work in improving students' study skills.

The most productive assessment method uses an ecological approach, involving classroom observations, analyses of work samples, consultations with teachers and parents, student interviews, observing the student at work and having him describe his work method, and examining the student's notebooks, assignment books, and completed work. One must precisely identify areas of weakness to design effective remediation. This chapter groups study skill assessments and interventions into five areas: Basic Skills, Listening Skills, Reading Study Skills, Reporting Skills, and Test-Taking Habits. In addition, questions to supplement clinical interviews are provided, as well as a checklist of classroom characteristics facilitating good study skills. Effective remediation requires that the school psychologist, teacher, and parent work together closely to determine appropriate procedures, designate responsibilities, and design techniques to encourage generalization.

Best Practices for Increasing Academic Learning Time

Maribeth Gettinger
University of Wisconson–Madison

OVERVIEW

There continues to be considerable interest among educational researchers in examining time variables that are related to school achievement. One of the most consistent findings from research on learning time is that the amount of time students devote to active engagement in appropriate learning activities is significantly related to their achievement outcomes (Gettinger, 1986). Time has been accorded special significance by teachers and classroom consultants because of the well-documented relationship between time and learning. In addition, time, unlike less malleable determinants of achievement such as student ability, is viewed as a manipulable facet of school and classroom life that teachers are able to control. Indeed, research has shown that certain teacher behaviors and classroom practices can, in fact, influence the amount of time students are engaged in learning (Brophy & Good, 1986).

For classroom teachers, time is a limited and critical resource. There is only a finite amount of time in which to accomplish multiple educational goals, often for academically diverse groups of students. Although most teachers acknowledge the importance of using instructional time efficiently and effectively to improve learning, many may not fully appreciate or understand their own role in the management of classroom time. According to Goodman (1990), "the master variable of pedagogy is the amount and intensity of student engagement in appropriate learning tasks. Effective learning time depends heavily on the atmosphere of the classroom and on the teacher's leadership skills in managing the instructional tasks" (pp. 10–11). This statement underscores the significance of instructional time, appropriate learning tasks, and teachers' instructional and managerial skills for enhancing classroom learning.

One recommendation that emerges from recent research on instructional time is that teachers should try to minimize the extent of discrepancy between allocated learning time and engaged learning time in their classrooms. Such a recommendation, however, is not helpful unless classroom consultants can provide more specific guidelines about how to engage students and how to use instructional time effectively. Because of their evolving role as classroom-based, instructional consultants, school psychologists need to be aware of, and must be able to apply, findings from research that link specific teaching practices with high levels of engaged learning time. The purpose of this chapter is to describe best practices for working with classroom teachers to improve their use of instructional time to maximize student engagement and achievement. In accordance with the problem-solving approach adopted for this volume, the following discussion of basic considerations focuses on defining academic learning time and its components, and on describing procedures for assessing current levels of learning time, for setting reasonable goals for change, and for monitoring progress or improvement. The subsequent section on best practices describes strategies for increasing academic learning time that can be offered to classroom teachers through collaboration and consultation with school psychologists.

BASIC CONSIDERATIONS

School psychologists' ability to help teachers maximize academic learning time among students is predicated on several basic considerations. The first is an understanding of the concept of *academic learning time* (ALT) and its relationship to learning. Of all the time variables that have been investigated in recent years (e.g., time-on-task, allocated time), ALT has been shown to be most consistently associated with students' achievement (Fisher & Berliner, 1985). A complex concept related to a number of other dimensions of instructional time, ALT is defined as the portion of instructional time allocated to a subject-matter area during which students are engaged actively and successfully in instructional activities. Three individual elements collectively constitute ALT: (a) allocated time, (b) engagement time, and (c) success rate.

BEST COPY AVAILABLE

Allocated time is the amount of instructional time made available by the teacher for learning. It represents the upper limit of students' in-class opportunities to be engaged in learning activities. One requirement of effective teaching is to be able to allocate and organize instructional time effectively. Because teachers differ in their ability to manage instructional activities, allocated time may vary considerably across classrooms. Furthermore, allocated learning time may differ from student to student even in the same classroom because of variable outside-of-class time that learners devote to individual study or homework. For example, one student may self-allocate 20 minutes of study time for spelling every night, whereas another may only spend 5 minutes. Over a five-day period, this will result in a range of allocated study time from 25 to 100 minutes. For purposes of this chapter, only in-class, instructional time allocated by teachers will be considered.

Engagement rate is the proportion of allocated instructional time during which students appear to be learning, as evidenced by observable behaviors such as paying attention, completing written problems, or interacting with peers about assigned work. Whether students are engaged in learning depends not only on how academic content is presented by the teacher and for how long, but also on how much time students actively study it. Teachers do not produce active or engaged learning time directly; they provide opportunities to learn that students then exploit to a greater or lesser extent. Even in classrooms where students have the same opportunity to learn, disparities exist among students in their individual levels of engagement. In one sixth-grade classroom, for example, Smyth (1985) found that engagement rates among individual students ranged from as low as 38% of the allocated time to as high as 78%. When these rates are extrapolated to an entire school year, the differences between low- and high-achieving students in their accumulated hours of engaged learning time could be expected to range from 46 hours to 280 hours.

Although they are important classroom variables, neither allocated time nor engagement rate impute any specific value to the learning activities involved. For example, it is possible that some students may spend time engaged in learning activities that are so easy or so difficult as to be of little educational value. Notwithstanding the need to provide a certain amount of challenging material, research indicates that children gain most of their engaged learning time when they experience a relatively high level of success (Myers, 1990). In addition, students spend more time engaged in tasks that match their current level of knowledge and skill. Therefore, *success rate* is another critical component of ALT.

Success rate represents the proportion of allocated instructional time that students are engaged in tasks providing high, medium, or low levels of success. The ratio between the number of correct responses and the number of incorrect responses on a designated assignment constitutes the success rate for the student's performance. Although success rate guidelines vary across different researchers, a high success rate is commonly viewed as at least 80% accuracy, in such assignments as responding to teachers' questions during class discussions, completing math problems, or spelling words. In other words, students should encounter a preponderance of success in their daily work, and the ratio between correct and incorrect responding should favor success by at least a 4-to-1 margin. Ensuring a high success rate depends, in part, on the teacher's ability to match the difficulty of learning tasks to students' ability level. In fact, the teacher's ability to assess the knowledge and skill level of individual students relative to academic tasks is a strong predictor of ALT.

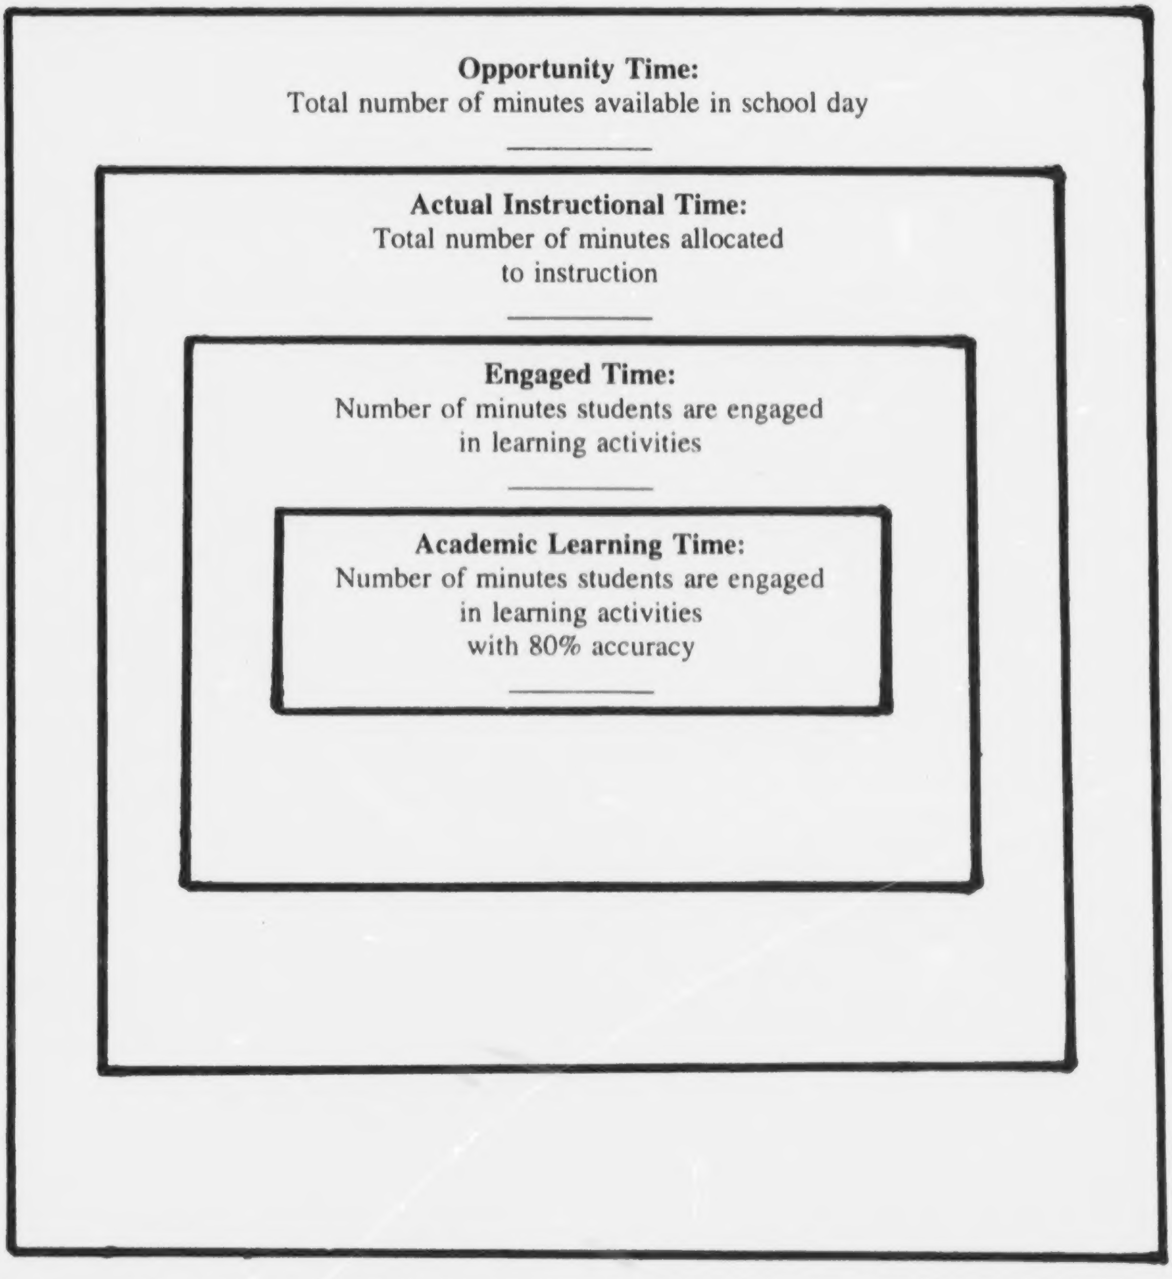
In light of its complexity, efforts to increase ALT require that (a) teachers maximize their allocations of instructional time, (b) students have high engagement rates, and (c) students experience a high level of success on assigned academic tasks. Although it is not possible to prescribe an optimal level of ALT, the consistency of the relationship between ALT and achievement across a number of different studies suggests that the more ALT a student experiences, the greater the learning that presumably has occurred.

A second basic consideration for school psychologists is familiarity with assessment strategies for evaluating use of instructional time in classrooms as well as academic learning time among students. Such an undertaking, seen as a problem-solving task, entails helping teachers to analyze their own use of time and to target potential areas for change.

Figure 1 presents a framework for examining time use in classrooms that includes the three elements of ALT described above. First, allocated time is examined as a function of two variables: (a) opportunity time, which is the total amount of time available in the school day, and (b) actual instructional time, or the amount of opportunity time that is actually allocated to instruction by teachers. Second, engaged time is examined as a portion of allocated time; this requires an estimate of the amount of time during which students are actively involved in learning activities. Finally, ALT, or the amount of engaged time in which students are experiencing at least 80% success, is examined.

Best practices for increasing ALT begin with a comprehensive analysis of ALT in schools and individual classrooms using the framework presented in Figure 1. Such an analysis can serve to heighten teachers' awareness of their use of instructional time and to help them see for themselves that a considerable loss of potential learning time can occur during the day. Two types of time analysis procedures can be conducted. For the first procedure, the school psychologist facilitates discussions among small groups of teachers who teach similar grade levels or subject-

FIGURE 1. Framework for analyzing instructional time use.



Opportunity Time:

matter areas. Teachers work through the framework in Figure 1 using their existing knowledge about school operations and estimates of how they allocate class time. As a group, the teachers begin by placing the number of minutes available in a school day in the outer box. Then they examine ways that potential instructional time is lost (e.g., lunch, recess, transitions, early dismissals). When this lost time is subtracted from opportunity time, the amount that remains is available instructional time. This analysis procedure continues through the various dimensions of time until a number is determined for the inner box (ALT). Mutual analysis of time usage among teachers in small groups can provide a forum for collective dialogue on ways of modifying classroom practices in order to increase ALT.

The second procedure entails a more extensive, individualized analysis of time use in classrooms. As with the first procedure, this analysis uses the framework presented in Figure 1. However, rather than guide discussions among small groups of teachers to arrive at estimates of time allocations at the four levels, school psychologists devise and implement strategies to measure actual time usage in the individual classroom. Although this is more time-consuming than a group procedure, teachers may be more likely to view time analyses as useful when data are included from their own classrooms. Assessment strategies include reviewing existing documents such as lesson plans or daily/weekly schedules, having teachers keep personal logs or diaries of how they use class time during a typical 1- or 2-week period, interviewing teachers and students about time usage, and conducting observations of student engagement and success rates during classroom activities. When possible, it is useful for teachers to collect this type of information themselves. For example, having teachers identify and observe one or two "typical" or above average and below average students during ongoing activities can provide rich and revealing windows on students' engagement in learning.

Because of the importance of analyzing instructional time use on the basis of student engagement and success rate, school psychologists will need to develop protocols to assess the extent of students' engagement in the teaching-learning process. Figure 2 provides one example of a format for integrating data on student engagement and success.

Another self-monitoring procedure that teachers can use to analyze their class schedules and time usage was recommended by Paine (1983). For this procedure, teachers construct a written schedule of all classroom activities and compute the percentages of available class time they devote to each activity. Activities are then ranked from highest to lowest based on the percentage of time devoted to each one. These rankings indicate teachers' priorities for time use, as reflected by their schedules. It is also useful for teachers to rate overall achievement among students in each curricular area on their schedule. This allows them to determine whether there is a relationship between achievement and the amount of time they allocate to various areas. This type of classroom schedule analysis is useful in finding ways to increase or reallocate time devoted to particular activities or content.

Subsequent to an analysis of the use of classroom time, it is helpful to pursue with teachers their organizational or teaching activities. The same duration of allocated learning time and similar engagement and success rates may yield quite different learning outcomes. This occurs because some ways of organizing instructional time are more efficient than others for learning. For example, one researcher asked a group of middle school teachers to sort statements describing teaching activities that ranged from "keeping on track" activities to "squandering time" activities (Murphy, 1992). In effect, all of the activities could be organized along a managerial dimension of being teacher-controlled versus student-controlled. Teacher-controlled activities were more structured and kept students engaged ("on track"). The activities had a definite goal and a definite time in which to achieve the goal. Examples included note-taking by students during a teacher-presented lesson and accomplishing assigned problems while seated at their desks. Student-controlled activities, on the other hand, had greater potential for the squandering of time, but they also had relatively higher intrinsic benefit and motivational value for the students. Examples included students' taking measures for a science experiment and discussing readings in a small group. Inherent in student-controlled learning activities are long-range gains relative to motivation and engagement that must be balanced against the potential immediate loss of instructional time. According to Wang, Gennari, and Waxman (1985), effective management of classroom activities integrates both types of activities (termed "prescriptive" and "discovery" learning activities in their model of classroom instruction) in order to maximize students' involvement in learning.

In sum, school psychologists can initiate teachers' thinking about instructional time through an analysis of the three elements that compose ALT by using the framework shown in Figure 1. Based on evaluations of current time use and overall management of classroom activities, best practices for increasing ALT in individual classes can be identified and implemented.

BEST PRACTICES

The nexus between ALT and learning outcomes, in many respects, is a commonsense notion. Classroom teachers often acknowledge that the proportion of time students spend actively and successfully engaged in learning is positively related to their achievement. Confirmation of commonsense notions, however, does not necessarily imply widespread or common acceptance. Many teachers may not possess the necessary skills or knowledge of instructional approaches that have been shown to increase ALT. In addition, they simply may not recognize the long-term impact of their allocations and use of classroom time. The way in which teachers choose to allocate time and the way in which their students are allowed to spend that time provide insights into the values teachers hold with respect to learning. Thus, it is important for school psychologists to target teachers' skills, knowledge, and values in their efforts to work collaboratively with teachers to increase students' ALT.

In recent years, research on effective instruction has focused on identifying demonstrably best prac-

FIGURE 2. Protocol for evaluating engagement and students' success levels during instruction characterized by content, instructional activity, grouping structure, and allocated time.

	Number of Students Engaged [observed every 5 mins.]	Achievement: Productivity	Achievement: Success rate

tices for increasing ALT. Several proven methods of classroom management and instructional approaches can be implemented to increase ALT (Hawley & Rosenholtz, 1984). Research has demonstrated that teachers can be provided with direct training or consultation related to specific instructional procedures that, if implemented, will lead to more engaged learning time and higher achievement among students.

Much of the research can be organized around three paradigms: (a) the process–product paradigm,

TABLE 1
Best Practices for Increasing Academic Learning Time

Process-Product Research Paradigm: Interactive Teaching Behaviors

- Academic focus
- Interactive instructional activities
- Active academic responding
- Teacher-selected activities
- Student–teacher interactions
- Delivery of instruction approaches
- Classroom management strategies

Classroom Ecology Research Paradigms: Structure of Learning Activities

- Adaptive instruction
- Flexible grouping practices
- Integrated curriculum approach

Mediating Process Research Paradigm: Student Strategies

- Cognitive-behavioral training
- Independent learner strategies
- Self-management

which looks at the relationship between teachers' behaviors and students' learning; (b) the classroom–ecology paradigm, which considers the structure and characteristics of the classroom as important factors in explaining students' learning; and (c) the mediating–process paradigm, which views variations in learning as a function of activities carried out during the learning process; these activities are viewed as mediating between teacher behavior and student learning outcomes. All three strands of instructional research have contributed to our understanding of classroom learning. Best practices for increasing ALT, therefore, can be discussed relative to three general groups of recommendations: (a) teacher behaviors, (b) structural arrangement of classrooms and learning situations, and (c) student strategies and self-monitoring. The following sections present a number of teaching practices and management strategies that are supported by research as strongly associated with ALT. These are intended to serve as guidelines for school psychologists in their role as classroom consultants. These best practices for increasing ALT are summarized in Table 1 and discussed below.

Teacher Behaviors

Certain teacher behaviors and instructional management strategies can have an impact on student behavior so as to promote ALT. Collectively, these behaviors reflect what has been termed a directive or *interactive teaching style*. Interactive teaching encompasses a constellation of specific teaching behaviors related to high levels of ALT.

The primary characteristic of interactive teaching is a strong *academic focus*. Academic focus is reflected in the amount of time devoted to academic versus nonacademic activities and in the type of instructional interaction that prevails in the classroom. Rosenshine and Stevens (1986) described classrooms with a strong academic focus as incorporating the following teaching characteristics: (a) systematic, goal-related activities; (b) lessons and content related to attaining specific goals; (c) rapid pacing of lessons; (d) ready availability of teaching materials; (e) high levels of student participation and responding; (f) efficient use of time; (g) student accountability for homework; (h) frequent monitoring of students' performance through weekly and monthly tests; and (i) positive encouragement of good work habits. There is some concern that a strong academic emphasis may be gained at the expense of affective outcomes. Research indicates, however, that classrooms with an academic focus are also characterized by warmth, friendliness, high levels of student motivation, and positive attitudes among students toward school and themselves (Berliner, 1988).

The nature of teaching activities and instructional methods is also related to ALT. Research suggests that not all academic activities are of equal instructional value. Specifically, *interactive activities*, such as discussion, review, reading aloud, and providing supportive [illegible] corrective feedback, are more positively related to ALT than are noninteractive activities, such as silent reading or assignment of seatwork. Research by Stallings and her colleagues (Stallings, 1980) has consistently shown that interactive instructional activities are associated with higher levels of ALT and achievement. Spending a greater proportion of time in interactive instructional activities may be initiated after teachers first analyze their classroom activities and then think about ways to convert or modify some activities to be more interactive. For example, math problems might be solved collectively by small groups of students rather individually as an independent seatwork assignment.

Another important aspect of interactive teaching is the nature of children's participation or involvement in academic activities. Children's participation during instruction can be characterized as either active or passive. These two types of responding are not equally beneficial for students or equally related to ALT and achievement. *Active academic responding* on the part of students is related to high levels of ALT (Anderson, 1984). Active responding involves children's practicing academic tasks (e.g., answering a question, reading a text, performing the steps in solving a problem). Examples of passive responding include general attending behavior, such as listening to another child read or watching another child complete a problem. ALT can be increased by incorporating some element of active student responding into every learning activity and encouraging oral responses from all students during group lessons and discussion. Again, a careful analysis of classroom tasks might reveal how active responding can be built into particular activities. For example, students could be encouraged to ask questions and respond to answers from peers as well as answer their classmates' questions, rather than having the teacher do so. Beyond fostering active participation, this strategy allows students to practice good listening skills. In addition to maximizing ALT, active academic responding on the part of children affords the teacher numerous opportunities to monitor the students' progress and provide corrective feedback about their performance.

Inherent in an interactive teaching style is the emphasis on *teacher-selected activities*. Research has consistently shown that students are engaged more and learn more when the teacher, not the students, selects and directs learning activities (Brophy & Good, 1986). Although students continue to take responsibility for their own learning, in an interactive teaching model, the teacher has leadership in determining and structuring learning activities for students.

Interactive teaching, as the name implies, involves a high level of *student–teacher interactions*. And frequent student–teacher interactions are specifically associated with high levels of ALT. As the teacher interacts with and directs questions to students, it is important that all children be given an opportunity to participate, not just those who are eager to respond. There is ample evidence that low-functioning students, in particular, accrue lower amounts of ALT because of fewer student–teacher interactions and fewer opportunities to respond (Thurlow, Ysseldyke, Graden, & Algozzine, 1984).

Many teachers state that maintaining engagement among all students during whole-class discussions is one of the most difficult aspects of interactive teaching. An effective questioning technique for circumventing this problem is for the teacher to direct questions to students randomly or in ordered turns, moving in sequence among all children in the group or class. Random selection in calling on students has the effect of keeping students attentive, particularly if the teacher occasionally returns to a student who has recently answered a question.

Another recommendation for maintaining engagement during student–teacher interactions is to wait at least 5 seconds before providing a correct answer to a question or calling on another student to respond. Research indicates that, on the average, teachers wait only 1 second for a student to respond (Rowe, 1974). To make this finding more believable, school psychologists should ask teachers to consider a typical type of question they might ask in their classroom and then silently count to five to experience a 5-second wait. If teachers want to maintain students' engagement and increase willingness and ability to answer questions, they must provide all students adequate time to answer. When teachers fail to provide sufficient time for responding, students may learn that they can remain uninvolved simply by failing to respond immediately.

A final aspect of student–teacher interactions is feedback. Children perform better and maintain high levels of ALT when they are given frequent feedback concerning how they are doing. Feedback to students that is characterized by specificity and academic relevance has been found to be highly associated with ALT. Thus, information given to students about their performance should indicate whether responses are correct or incorrect as well as provide specific suggestions for rethinking or redoing the work. Modeling appropriate feedback to students and effective student–teacher interactions by classroom consultants is an effective way of demonstrating to teachers the positive effects of these modifications on ALT.

A number of procedures related to the actual *delivery of instruction* in an interactive teaching approach also influence levels of ALT among students. For example, valuable instructional time is often lost in classrooms because teachers may have difficulty obtaining students' attention and getting started on lessons, or making smooth transitions between activities. Several strategies can reduce the amount of time needed to start new activities. One is to select a discriminative stimulus or cue that foreshadows a new activity. The phrase or cue can be thematic, may vary every month, and can be selected by the students themselves. Teachers should be encouraged to record the time it takes students to pay attention following the cue, and to monitor the reduction in the amount of time needed across weeks. Children can be challenged to reduce the time it takes the class to get ready for a lesson from the previous time. Another guideline is to wait to begin instruction until everyone is paying attention in order to prevent having to repeat presentation of content or directions for completing work. The amount of time targeted for students to "get ready" should be optimal, allowing slower students sufficient time to attend while maintaining readiness among the faster ones.

Still another recommendation related to the delivery of instruction is to stimulate interest in a new lesson or activity by relating it to a previous lesson or experience, or starting with a motivating activity to make the initial contact with the lesson as positive as possible. We know that students' motivation and engagement in tasks can be heightened by simply indicating why the material is being learned and by suggesting ways in which the new learning may be related to other events or experiences in their lives. Another effective approach to delivery of instruction is to give precise instructions that clearly describe the goals, the activities to be completed by students relative to their goals, and the evaluation procedures associated with the lesson being presented. A significant amount of lost time stems from students' not knowing how they are to proceed with assigned tasks. To ensure that students understand instructions, teachers can ask students to paraphrase the directions, state any problems that might occur in understanding or following them, and make an oral or written commitment to follow the directions carefully. In addition, whenever possible, directions should be written and placed where they can be seen and referred to continuously by students as needed. It may also be necessary to distribute outlines, definitions, or study guides to help students organize their thoughts and focus their attention on lessons or assigned work.

Finally, interactive teaching is characterized by effective *classroom management strategies* designed to conserve instructional time. For example, the best management strategy for noninstructional transitions is to instill a routinized awareness in students of the classroom rules and procedures for such activities. Teachers whose classrooms are examples of good management invest considerable time and effort, particularly early in the year, in training students in the rules and procedures necessary for smooth classroom operation. The degree of loss of instructional time is closely tied to the teacher's management skills. Therefore, teachers may benefit from consultation or direct training in leadership and organizational skills as well as guidelines for establishing expectations for students with clear contingencies for performance. Some time loss to managerial needs is inevitable in every classroom, but the goal should be to keep lost time to a minimum. An analysis of time usage as described earlier can facilitate targeting areas for change.

In summary, interactive teaching occurs when the classroom teacher assumes a central, active, and direct role in the instructional process. Teachers who emphasize academic goals and display high levels of actual involvement with students on learning tasks generate high levels of ALT. The teacher selects the academic activities and leads students through academic tasks to accomplish specific instructional objectives. There is a high level of student–teacher interaction, most of which is initiated by the teacher. The majority of instructional time is devoted to the teacher's presentation, explanation, and demonstration. Practice, feedback, the teacher's questioning, and review of activities also figure prominently in daily instruction. The teacher monitors student progress and provides corrective feedback. The teacher holds and conveys high expectations for student performance. Finally, clarity of directions on how to undertake learning tasks, praise, and feedback on correctness of responses are all associated with high levels of ALT.

Helping teachers to think about their activities may contribute to or detract from students' engagement is a critical component of school psychologists' efforts to increase ALT. School psychologists can take an active role in encouraging teachers to evaluate their own classrooms as to how effectively time is being used. A problem often associated with recommendations to enhance ALT is a tendency, even with acknowledgment of their value, not to implement them in actual classroom teaching. It is unreasonable for school psychologists to expect that teachers will adopt several new teaching methods at one time. Therefore, it is important to encourage classroom teachers to identify one to three approaches that maximize ALT during instruction. In collaboration with a school psychologist, teachers can write one specific method that they do not currently use and that they believe could be implemented in their classroom to help increase engaged learning time among their students. For example, a teacher might write, "Place directions where they can be seen and referred to by students." After identifying and formalizing viable strategies, teachers and school psychologists together should develop a plan for implementing the procedure, specifying when teachers will begin using the method, the length of time for implementation before evaluating its effectiveness, and a method for evaluating effectiveness.

School psychologists can play an important role in helping teachers collect data to evaluate the effectiveness of a new approach. Whenever possible, teachers should generate some form of evaluative data to assess the results of using new methods. For example, during a question-and-answer period when a teacher is implementing a 5-second wait strategy to increase engagement among students, the school psychologist or teacher can count the number of hands that are raised to answer each question and compare this with the typical number of students who raise their hands during a time when a 5-second wait strategy is not used.

Structural Arrangement of Classrooms and Learning Situations

Increasing ALT among students also requires incorporating innovative practices to restructure and reorganize classroom learning that extend beyond individual teacher behaviors. The heterogeneity of most classrooms today poses a unique challenge to teachers in their efforts to increase ALT among all students. Therefore, school psychologists should work with teachers through individual consultation or in-service training to structure learning activities in accordance with approaches that have been shown to promote high levels of ALT and achievement among diverse students. Collectively, these approaches are called *adaptive instruction*. Adaptive classrooms are designed to accommodate a wide range of individual differences among students. Conceptually, adaptive instruction is viewed as a two-way enterprise between the classroom environment, on one hand, and the students themselves. Hence, efforts to adapt to student diversity have a dual focus: (a) to structure the learning environment to accommodate students' needs, and (b) to provide students with independent learning strategies to improve their capability to adapt to the demands of the classroom. In this section, two strategies that entail the modification of classroom structure are described: (a) flexible grouping practices, and (b) integrated curriculum approaches. Student strategies for independent learning are discussed in the final section.

Flexible grouping practices represent a resolution to a paradox that school psychologists are likely to confront as they assist teachers in attempting to maximize ALT. Whole-class instruction has the potential for enhancing overall engagement by virtue of the teacher's ability to collectively monitor and foster active responding among all students at one time. Whole-class instruction, however, may not provide individual students with sufficient opportunities to respond or with material at an appropriate level of difficulty in order to ensure the high success rate necessary for ALT. Individual seatwork, on the other hand, lends itself to providing high levels of student success, but it may minimize students' engagement. Furthermore, individual teaching and learning activities may not always represent the most efficient use of allocated instructional time. Teaching students in small groups or having students work cooperatively in groups can circumvent some of the problems inherent in individual or whole-class teaching.

The key to grouping practices that are successful in increasing ALT is flexibility. In other words, membership in groups should change on the basis of specific needs of students and the nature of the learning activity. The decisions made about grouping for instruction are important because of their management implications and instructional impact. For example, heterogeneous grouping arrangements foster high levels of engagement in activities that are designed to be cooperative — that is, activities in which students coordinate their individual skills and efforts to achieve a group goal. Typically, exploratory tasks lend themselves to heterogeneous grouping. These are tasks designed to foster social development and to enrich or apply basic skills, such as playing games or solving problems. For group activities to maintain a high level of student involvement, tasks must be selected to allow each student to function as a contributing member. Every student needs the opportunity to be both challenged and successful on the learning task (necessary components of ALT), which may require adding easier or smaller components for low-ability students as well as more difficult or complex ones for high-ability students.

Homogeneous grouping, on the other hand, allows students to work on material according to their achievement level. Homogeneous grouping arrangements allow the teacher to provide assistance geared to the level of students in the group, thus maximizing their ALT. Prescriptive tasks are more appropriate for homogeneous groups, such as completing independent seat work problems, receiving teacher-directed explanations or instruction, or being tutored in basic skills.

Table 2 provides an example of a math lesson that incorporates flexible grouping to increase individual levels of engaged learning time among heterogeneous learners. By selectively incorporating whole-class, small-group, and individual teaching, the classroom teacher is able to increase the efficiency of the time allocated for teaching this math lesson. An important role for the classroom consultants is to work collaboratively with classroom teachers to adjust lessons and teaching formats to be more flexible.

In sum, decisions about how children are best grouped for instruction to maximize ALT, particularly children who are experiencing academic difficulty, should reflect teachers' knowledge of engagement patterns in their classrooms and of how to make the best use of instructional time. Each grouping option impacts differently on students' engagement. Whole-group instruction may be easiest to manage because the teacher can supervise all students at one time. Small-group instruction entails greater management skills on the part of the teacher, but it is more effective in engendering high levels of student–teacher interaction. Finally, individualized instruction facilitates matching instruction to each child's unique needs and skill level to maximize success rate. Efforts to increase ALT reside in the careful and selective application of whole-class, small-group, or individualized teaching according to the particular needs of students.

TABLE 2
Example of Flexible Grouping for Math Instruction

Grouping	Activity
Whole-class grouping	Explain concept of two-digit subtraction with borrowing.
Heterogeneous groups	Play game "Break the Bank" in groups of 4–5 students. Game provides opportunity to perform operation at concrete level.
Homogeneous groups	Independent skill practice on computation problems.
Individual instruction	Individual assistance from teacher on computation problems as needed.
Heterogeneous groups	Choice of enrichment activities: (1) Create own game. (2) Write own story problems.
Whole-class grouping	Review concept. Student presentations of group enrichment activity product.

The recommendation for an *integrated curriculum strategy* emerges from the lack of adequate instructional time for content-area teaching that is often encountered, particularly in the upper elementary grades. Lack of instructional time is often identified as a major limiting factor in improving the quality of instruction in content areas such as science, history, and social studies. For example, within the restricted instructional time available, many elementary science programs include only assigned reading activities in science textbooks. Educators attribute the generally negative attitudes displayed by students at the secondary level toward specific content areas, such as science and history, to the lack of in-depth instruction in elementary school that includes hands-on activities. At the same time, educators stress the importance of content-based reading activities as vehicles for developing applied reading comprehension and thinking skills, but they also acknowledge the limited amount of instructional time available for such activities.

An integrated curriculum strategy that teaches applied reading skills across a range of content areas is one approach to circumvent this problem – that is, to increase ALT in content-area reading and, simultaneously, provide additional time for in-depth thinking activities. The goal of such a strategy is to improve the quality of both the content-area and reading instruction within an integrated time frame that reallocates the combined instructional time assigned to all curriculum areas. For example, Romance and Vitale (1992) described an integrated curriculum strategy designed to increase the time allocated for in-depth science teaching by replacing the district-adopted basal reading program with science-content-based instruction that concomitantly facilitated reading comprehension skills. They found that ALT in both science and reading activities increased for students as well as their achievement, attitudes toward science and reading, and academic self-confidence.

Student Strategies and Self-Monitoring

The concept of ALT implies instructional, managerial, and cognitive-behavioral concerns. Achievement is in large part a function of discrepancies between time allocated by teachers for learning and time spent by students cognitively engaged with the content of learning tasks. Even when students appear to be actively engaged in learning, their ALT may not be optimal because they may have difficulty allocating attention efficiently to information within tasks. This may be particularly true for students with learning problems whose slower rates of acquisition and subsequent lower achievement have been linked to inefficient cognitive-behavioral strategies (Goodman, 1990). Best practices for increasing ALT implicate procedures to improve not only how teachers allocate and structure available time (instructional efficiency), but also how students use instructional time (cognitive efficiency).

According to Corno and Mandinach (1983), cognitive engagement refers to students' processing of task-oriented information as well as some degree of cognitive regulation. To maximize cognitive engagement, students need to receive training in general problem-solving skills. By teaching students to attend to and apply strategies common to all problem-solving situations, teachers can increase students' self-regulated ALT across several different learning tasks. For example, Hallahan and his colleagues (Hallahan et al., 1983) have shown that when students with learning disabilities are trained to self-monitor and self-record their attention during independent seatwork periods, they demonstrate higher levels of on-task behavior as well as gains in academic productivity (number of correct responses per unit of allocated time). Gerber (1988) obtained similar positive effects on both level of attending and achievement when students were taught to monitor the quality of their performance (e.g., "Am I checking my spelling?") rather than simply attention to the task (e.g., "Am I paying attention?"). Finally, Palincsar and Brown (1984) concluded from a series of studies that to be successful, cognitive training must direct students to be cognitively engaged during learning tasks, must provide corrective feedback on appropriate use of trained strategies, and must provide instruction concerning when and why such strategies should be *applied*.

The systematic application of cognitive-behavioral training (CBT) as part of instruction that enhances self-regulation during learning can increase ALT. By providing a self-managed problem-solving routine, CBT reduces the difficulty of tasks in terms of information load. If students can be taught to approach learning tasks in a more structured, organized fashion, it is reasonable to expect that they also will be more efficient with their learning time. By facilitating students' ability to organize information more efficiently, CBT increases the probability of correct responses (high success rate) during learning activities.

Another factor that contributes to an increase in individual ALT is students' *independent functioning* in the classroom. To try to manage the range of ability levels in heterogeneous classrooms and to enable each child to exhibit maximum ALT for specified time periods, a systematic approach toward developing independent learners is necessary (Cohen & de Bettencourt, 1988). Students can be taught directly to guide themselves through much of their day with minimal assistance from a teacher and with minimal loss of engaged learning time.

There are several best practices for teaching and encouraging students to become independent learners. For example, students able to perform tasks may not approach them systematically, which often results in time lost while they are getting started on an assignment. Teaching children a systematic task approach can be accomplished by using a step-by-step sequence that helps children structure that behavior. The procedure may consist of having students ask themselves a series of questions listed on an individualized job card (e.g., What materials do I need?; How much time do I have?). Before beginning an assigned task, students use their job cards to determine what needs to be done and whether they have the knowledge, skills, materials, and time to complete it.

Another way in which students can enhance the efficiency of classroom use of time is through *self-management*. A growing body of research shows that students are capable of fulfilling some instructional functions typically carried out by the teacher. Training students to assume a degree of responsibility for their own instruction has been shown to increase ALT (Cole, 1987). Furthermore, to the extent that students can self-manage aspects of their own instructional program, teachers will have greater flexibility in the use of their time for other tasks and for students who may require additional instructional time. One example of self-management is the use of self-correcting techniques. Several types of self-correcting materials have been shown to be effective, including the use of flash cards, answer tapes, overlays, or checking stations with scoring keys.

In summary, students are capable, given the proper training and supervision, of assuming a degree of instructional autonomy through the use of CBT, independent learning strategies, and self-management. The use of these procedures consistently produces enhanced student attending and ALT.

SUMMARY

There are several approaches to classroom management and instruction that have been shown to maximize academic learning time, which directly affects students' achievement. Best practices for helping teachers increase their students' ALT begin with an awareness of the components of ALT, an understanding of the relationship between ALT and achievement, and an analysis of use of classroom time to target specific activities, content areas, or instructional periods for change. Allocating more time to instruction alone does not ensure that students will exhibit higher ALT and achievement. If, for example, academic tasks are so difficult that students do not experience sufficient success during their study time, providing more time to the same tasks will fail to have a positive effect on either students' ALT or achievement.

Best practices for increasing ALT have emerged from three separate strands of instructional research. The first is process–product research, which identifies teachers' behaviors (process) that are associated with higher ALT and achievement (product). An interactive teaching style, for example, is associated with high levels of ALT. The second strand is classroom environment research, which examines the way in which classroom activities and instruction are structured. Flexible grouping practices and integrated curriculum approaches have been identified as procedures that foster higher levels of ALT. The third area is mediating-process research, which identifies students' mediating behaviors that are related to ALT. Specifically, cognitive-behavioral approaches, independent learning strategies, and self-management are student strategies that mediate between teaching and student behaviors that increase ALT. Through collaborative instructional consultation, in-service training, and direct modeling of specific procedures in classrooms, school psychologists can promote teachers' implementation of the best practices for increasing ALT described in this chapter.

ANNOTATED BIBLIOGRAPHY

Gettinger, M. (1986). Issues and trends in academic engaged time of students. *Special Services in the Schools, 2*(4), 1–17.
This article describes several theoretical views of time and learning, including Carroll's model. It provides a review of major empirical time-and-learning studies that document a relationship between academic learning time and achievement. Finally, it addresses the implications of research for increasing learning time among students.

Goodman, L. (1990). *Time and learning in the special education classroom*. Albany, NY: State University of New York Press.
The purpose of this book is to encourage and help teachers of students with special educational needs to analyze their own teaching and look for ways to improve their effectiveness for all students. In addition to providing an overview of research related to time and learning, the author derives many practical classroom applications from the research findings, including strategies for conserving instructional time and enhancing academic learning time among students with learning problems.

Paine, S. C. (1983). *Structuring your classroom for academic success*. Champaign, IL: Research Press.
This book was written for teachers and classroom consultants. It focuses on important management skills every teacher needs to keep students actively engaged in learning and to make the most efficient use of class time. A unique feature of this book's practical approach is the use of actual scripts that outline specifically how to implement techniques in classrooms.

Best Practices in Preventing Problems in Unstructured Situations

Ann Casey
University of Minnesota/Minneapolis Public Schools

OVERVIEW

All children need a certain degree of structure in order to maximize their ability to be successful in an environment. The degree of structure necessary varies based upon an individual child's needs. However, when groups of children are placed together, a certain degree of structure, including rules and consequences, is helpful so that there is a sense of orderliness. While individual teachers may maintain a highly structured classroom environment, less structure is typically evident in the large-group activities of lunch, recess, passing periods, and on the school bus. Problems are waiting to happen in these environments. Many classrooms usually have lunch and recess at the same time, so that the sheer number of students in a given place is substantially increased. If attention is not given to increasing the structure in activities where the numbers of children are increased, one can predict that some kinds of behavior problems will evolve. When problems do occur, they often carry over into the classroom environment because they were not resolved in the occurring environment. Thus, it is an excellent idea for school psychologists to assist schools in prevention.

BASIC CONSIDERATIONS

This chapter looks at the behavior of children in large-group settings: playground, lunchroom, school bus, and hallways during passing periods. Teachers often express concern about how children behave in these settings, and the degree to which prosocial behavior is exhibited in these settings can contribute to the overall climate or feel of a school. Rowdy lunchrooms contribute to the characterization of a school as rowdy. Further, even in the most structured classrooms, spillover effects of unsolved playground confrontations can contribute to classroom behavior problems. Thus, it behooves school psychologists to plan for and anticipate potential problems in these settings and devise systems to reduce behavior problems.

Functional analysis of behaviors in these settings can lead to helpful information for intervention planning. Specifically, a functional analysis requires investigation of antecedent, situational, and consequent events through systematic observation and interview. In more pragmatic terms, it is important to investigate the events that precede the problem behavior, occur concurrently, and follow a problem behavior. Situational and consequent events are fairly easy for most observers to spot; however, antecedent events are not always so obvious. Antecedents can consist of a wide variety of things such as stated rules, directions given, number of adults assigned to supervision, and the number of students in the setting. All these antecedent variables exist prior to a problem occurring and, thus, can be potential contributors to behavior problems. In the discussion that follows, interventions will be discussed as either antecedent or consequent events.

Consultation skills are extremely important for any school psychologist attempting to work with schools to solve problems occurring in large-group settings. Consultation can take place on two levels: a system level (e.g., school building) or an individual teacher level. Sometimes an individual teacher may request help for a particular student who is experiencing difficulty at lunch or recess; however, upon inspection and observation the school psychologist may find that a significant number of children, not just the one referred student, could benefit from an intervention. In any case, the features of collaboration and shared decision-making inherent in consultation are also important to successful intervention.

Behavioral interviewing as described by Bergan and Kratochwill (1990) is a good introduction to functional analysis of behavior through a behavioral consultation framework. The methods these authors describe provide one with questions that can be used to specify antecedent, situational, and consequent events.

BEST PRACTICES — SYSTEM INTERVENTIONS

For purposes of discussion, "system" as it is used in this section, refers to a school building. Most of the interventions discussed here apply primarily to elementary school buildings, although a number of suggestions could be adapted for use with secondary students. How does a school psychologist get involved in implementing interventions at the systems level? While there are a wide variety of ways, one of the best is to get involved in school-based committee work. Many schools are moving toward a site-based management approach to school governance. This philosophy requires more staff and parent participation in determining problems and solutions. Thus, if school psychologists become more involved in the site-based management of the school, they can influence the direction some of the intervention planning will take.

The environments of the lunchroom, playground, hallways, and school bus will be discussed here from a building level with attention to both antecedent and consequent events. In order to reduce behavior problems in these settings, it is recommended that plans be made to attempt to prevent problems as well as have plans ready to deal with behaviors when they occur. After the discussion of building plans for the playground, lunchroom, hallways, and school buses, further discussion and suggestions for individual students with behavior problems in these settings will be presented.

Lunchroom

Problem behavior during the midday lunch period can be annoying for both staff and students trying to enjoy their meal. If significant problems are occurring, one consequence-focused intervention would be to use a group contingency. Students could be reinfored with extra recess time following their lunch, if there are no altercations during lunch. While this intervention has a nice appeal due to the immediacy of the consequence, it is not as easy to carry out as one might think. Schedules often dictate the school day. Typically, several classrooms share a lunch period with each following a different schedule once the lunch-recess period is completed. Thus, it may not always be possible to deliver the reinforcer of extra recess because students are likely to miss something else of importance. If this can be worked out, this intervention is a potentially powerful one. A variation would be to divide the lunch room into teams, and use the group contingency for each team. This variation includes the element of competition and may help improve behavior in some instances.

Another consequent event to consider would be the use of reductive techniques such as loss of recess time for behavioral problems. While this intervention may be worth a try, its implementation may cause other problems. Many teachers believe that students need recess time to expend pent-up energy so they can then focus on the remainder of the school day. Thus, if one deprives students of their recess, more behavior problems might be evident in the afternoon. This is a hypothesis that could be tested.

A "timeout" lunch table could be set aside for violators of lunchroom rules. Throwing food, name-calling, and other disruptive behaviors would result in the children manifesting these behaviors being sent to this table. At this table, students would lose their talking privileges and be required to finish their lunch with no conversation. Because many students view lunch as a social activity, this punishment procedure might be quite effective in reducing behavioral incidents for a vast majority of the student body.

In many parts of the country with frequent inclement weather, the students are not able to go outside for a noon recess so the lunch period is often extended. This can create an undesirable situation for lunchroom supervisors. Students typically eat their lunches and still have 15 minutes or so of time on their hands. To prevent behavior problems in this scenario, schools should plan alternative activities for the students during the remaining time. Some suggested activities include showing entertaining videos in one part of the lunchroom and having board or card games available for students to play at the lunch tables. Team games could be devised requiring the participation of larger groups of children such as a spelling bee or a game of 20 questions. Because the weather is unpredictable, a file of activities should be prepared and available to lunchroom supervisors when needed.

Preventive-focused intervention procedures for the lunchroom focus on antecedent events. The lunchroom design and procedures can be devised in such a way as to minimize the likelihood of behavior problems. First, chaos can be avoided if all children enter the lunchroom from one point rather than multiple entrance points. For example, if the food line is at one end of the room, the door closest to the food could be designated as the entry point. All students would enter at that point, eliminating problems of multiple lines forming to get lunch. Coats and bookbags could be banned which should help diminish the problem of stealing food. Students could be assigned to specific tables so that supervisory staff could become acquainted with the students in their area. Enough staff should be deployed to the lunchroom so that no one person is asked to supervise more students than is feasible.

Playground

If a number of fights and scuffles are breaking out on the playground, it is a good idea to take serious account of the playground including some of the following aspects: the physical layout including a place for games requiring running and a place for students who choose not to participate in activities, ages of the students using the playground at the same time, number of supervisors assigned, and current playground rules. Playgrounds vary considerably in size and in the amount and kinds of equipment available. Given the financial constraints in which most school districts currently find themselves, it will be assumed that purchasing new equipment is not an option. A large space is optimal because the playground can then be divided into different play areas. For example, a soccer game can be played in one part of the playground while foot races are being held in another. Big kids could shoot baskets at one hoop, and smaller kids could be at a different hoop.

On smaller playgrounds, this luxury is not available, and games that require large spaces such as soccer are not possible. Staff will want to give serious consideration to whether running games should be allowed at all. Running in small spaces can be dangerous as well as prompt behavior difficulties when students start running into one another. Observing playground behaviors can help determine if running is contributing to behavior problems. If this seems to be the case, it might be in everyone's best interest to ban games of tag that promote random running. Foot races could still be held but would need to be confined to a specific area where only those racing were allowed.

If permanent playground equipment is minimal, other play options should be devised. Murphy, Hutchison, and Bailey (1983) found that organized playground activities in conjunction with logical consequences for misbehavior contributed to improved playground behavior. In the absence of a sufficient number of swings, slides, and jungle gyms, organized activities such as jumping rope, hopscotch, red rover, and captain may I, should be considered.

Playground staffing patterns are important. A sufficient number of staff need to be available in order that all parts of the playground are adequately supervised. Perhaps one of the better methods of supervision is to assign staff to specific playground zones. For example, one person would be in charge of the basketball court, another in charge of rope skipping and foot races, while another supervises students on playground equipment. A staffing pattern such as this works well because adults have specific assignments rather than having a more vague objective of supervising the playground. In addition to using a zone supervision approach, staff should be encouraged to roam throughout their zone rather than standing in one spot. Walking around and interacting with the children provides the students with the appearance of a more actively involved supervisor and contributes to a safer environment.

Consideration needs to be given to who will conduct the playground supervision. Often this role is relegated to paraprofessional staff. This can work well if some attention is given to training and preparing paraprofessional staff for this role. Knoff (1984) suggested using stimulus control techniques whereby the control exhibited by the classroom teacher is gradually transferred to a paraprofessional so that, ultimately, the good behavior exhibited in the presence of the teacher is also exhibited in the presence of the paraprofessional on the playground.

After consideration has been given to playground organization, activities, and supervision with the idea of preventing problems, a plan for handling the occasional playground behavior problem will still be required. Natural consequences seem to work well. Most children find recess a reinforcing activity and, thus, the loss of any recess time is viewed as punishment. For example, if a student is caught chasing after someone and this is a rule violation, the student would be told to take a 5-minute timeout. A timeout space could be designated by using a piece of chalk to draw a large circle on the blacktop. The student in "timeout" would need to sit or stand in the circle for 5 minutes. Some playgrounds have benches or fences that can be used for the same purpose. For more serious behavior problems such as deliberately hitting someone, a more serious consequence may be in order. Most school discipline policies have prespecified consequences for offenses such as this, and suspension may be appropriate.

Some schools are experimenting with alternatives to school discipline policies. Most notable in these efforts is the implementation of conflict-resolution programs. While mediation or conflict resolution can be used throughout the school day, one of the most helpful places for peer mediation to occur is on the playground. Peer mediation attempts to teach children negotiation skills so that they can mediate their own conflict rather than always relying on adult intervention or externally imposed consequences. A group of children are given intensive instruction in peer mediation. Once trained these students are assigned to the playground as peer-conflict mediators. Mediators are easily identified by the other students because of special t-shirts or badges they wear while on the playground. Mediators work in pairs and assist students having a conflict. The rules of mediation are straightforward, and both parties experiencing the conflict must first agree to mediation. Each party then has an opportunity to state his/her side of the story, and the mediators help the parties reach an agreement that is mutually acceptable.

Some schools using peer mediation have allowed school discipline procedures to be suspended if the parties can come to an acceptable agreement on how to resolve the conflict. For example, two students may end up in a fist fight due to name-calling between the two. A mediated solution is likely to lead to a real resolution of the presenting problem. Suspending the students from school provides a consequence that may diminish the future occurrence of the behavior, but it does not help resolve the original problem. Thus, the goal of peer mediation is to help students resolve their own problems — a skill that will be valuable in life.

School Hallways

Someone entering a school for the first time usually gets an immediate feel for the building climate by how the students behave in the hallways. Thus, hall behavior, although certainly only a small part of school climate, is not unimportant. Passing periods and arrival and dismissal times need to be structured in such a way that children are orderly and generally well-behaved in hallways. Arrival and dismissal times can be chaotic just by the sheer numbers of students in the hallways at one time. Prevention strategies which focus on arranging antecedents will be discussed first.

One of the first things to consider is traffic patterns. Kerr, Nelson, and Lambert (1987) found that traffic patterns in school hallways contributed to the noise level and behavior problems. Without specific direction, students can end up congregating, so that suddenly there are more students in one place than can be reasonably supervised. For safety reasons, this problem should be avoided if at all possible. Traffic patterns to some extent are dictated by the design of the school building. However, depending upon the number of entry doors and hallways in a school, a wide variety of traffic patterns can be established. If the goal is to prevent hallway behavior problems upon arrival, students should not be allowed to go to their lockers any way they wish. Rather, assign students a specific route to follow to get to their locker. Generally, the route should be the most expeditious one — or the shortest distance between the entry door and the lockers. Staff assigned to monitor the halls as the students enter for the day come to know the students who should and should not be in any given hall. For example, one hallway of lockers could be designated for sixth graders. Rather than taking any one of four staircases to reach this hallway, students would be told to use only the northeast stairway when arriving in the morning. This should cut down on students roaming the halls.

At dismissal time, many behavior problems could be avoided if classroom teachers escorted their students from their lockers to the school buses. Another consideration would be to use a staggered dismissal time. This might be preferred in a very large school where the hallways would have too many children in them if all were dismissed at the same time. The disadvantage of a staggered dismissal is that some children end up sitting on the bus for extended periods which might create another set of problems.

Bus Problems

The job of a school bus driver has been underestimated by many. Not only is the driver responsible for driving safely in all kinds of weather and traffic conditions, but the driver needs to ensure that students behave in such a way as to not hurt one another or distract the driver from the primary responsibility of driving. Ideally, school districts would hold inservice training programs on simple behavior management techniques that bus drivers could use. Such an inservice could include topics like group contingent reinforcement and timeout procedures. Campbell, Adams, and Ryabik (1974) found that the consequences of pulling the bus over to a stop (timeout) for any instance of unruly behavior was an effective intervention. Another study (Greene, Bailey, & Barber, 1981) demonstrated that a sound-recording device and accompanying light display installed on a bus were effective in reducing high noise levels on the bus. Even in the absence of sophisticated equipment, bus drivers could make listening to the bus radio contingent upon good behavior. When the bus becomes too noisy, the driver simply turns the radio off. When the behavior is under control, the radio goes back on.

BEST PRACTICES — INDIVIDUAL INTERVENTIONS

Many teachers complain of students who behave relatively well in a structured classroom environment but have special difficulty in the hallway, bus, or playground. In this section, strategies for interventions with individual students will be discussed. When only one or two children are experiencing a problem, a system-level intervention is probably not warranted. Thus, when planning an individual intervention, a problem-solving approach will be necessary. This involves defining the problem behavior in behavioral terms, measuring the frequency and/or duration of the behavior, designing an intervention, and monitoring the effects of the intervention upon the behavior.

Hallway Interventions for Individual Students

A typical problem reported by teachers is students who cannot keep their hands and feet to themselves and push, shove, and inappropriately touch others while walking or waiting in line. First, it is important to establish how much of a problem this really is. Baseline data could be gathered daily for several days. The exact data to be collected would consist of counting the number of pushes, shoves, and other inappropriate touches the individual student makes each time the class moves in the hall. These data would be aggregated for the day. Several days worth of data would be necessary to establish a good baseline because the number of times the class moves in the hall probably varies each day depending on the schedule. (See Hartman, 1984, for a description of behavioral assessment procedures.) Once the baseline is established the data can be reviewed to determine if a problem exists. Peer comparison data can be collected concurrently to determine how discrepant the target student's hall behavior is from typical peers. Reviewing the data can lead to one of three possible solutions: (a) low frequency and, thus, not really a problem; (b) low frequency, but high intensity when it does occur (e.g., a fight); and (c) high frequency and, thus, a problem to be solved.

For the purposes of this chapter, a problem of relatively high frequency will be discussed, and both antecedent and consequence interventions considered. From an antecedent point of view, the environment needs to be arranged in such a way as to avoid the occurrence of pushing, shoving, and the like. One such intervention is to have the student walk either at the front of the line or a few paces ahead so no one is within touching distance. Another antecedent approach would be to have the student always walk in the hall with his hands in his pockets or with her arms crossed in front of herself. This strategy would probably require prompting and reinforcement by the teacher but may be worth the extra effort if the student is compliant with the prompts. This is termed differential reinforcement of an incompatible behavior (DRI) approach: Having one's hands in pockets is an incompatible behavior with pushing and shoving.

Interventions focusing on the consequences would consist of either rewards for decreased inappropriate touching in line or punishment for continuation of this behavior. Punishment procedures alone are usually not in the best interest of children because they do not focus on teaching the appropriate behavior. Thus, either a response-cost procedure or a procedure with both rewards and costs is a better intervention. For example, one response-cost procedure would be to start the student's day with five tickets for hallway behavior. The student would lose a ticket for any instance of pushing, shoving, or hitting in the hallway. If there are any tickets remaining at the end of the day, the student could earn a reward. Once the student begins to earn the reward, the number of tickets available should be gradually diminished so that, ultimately, the student exhibits no pushing, shoving, or hitting in the hall.

Overcorrection can be a powerful consequence for misbehavior in the hallway. There are two kinds of overcorrection procedures: positive practice and restitution. Both might be useful depending upon the type of inappropriate hallway behavior being exhibited. In the case of a student running in the hall, a positive practice consequence could be applied. Every time the student runs in the hall, he/she is stopped and asked to return to the starting point and to walk in the hall. Depending on the frequency of the problem, the adult might have the student "practice" walking two or three times in a row. Overcorrection through restitution would be a good consequence for instances of vandalism such as drawing on lockers or ripping displays off hallway walls. In this case, the student would have to replace the display or remove the drawings from the lockers. Again, if the problem is of high frequency, the intervention might require the student to overcorrect by cleaning not only the locker drawn on but also all other lockers in the hallway with drawings on them.

Individual Bus Plans

Some students have particular problems managing their behavior on the school bus. Usually, this comes to the attention of the school after the problem has escalated and the bus driver can no longer stand the misbehavior and asks to have the student suspended from the bus. Ideally, bus behavior problems would be dealt with before they become this severe. The bus driver is usually the only adult on the bus except for those cases where an educational assistant has been assigned to ride the bus with special education students. In either case, designing bus plans for individual students requires one to consult with the driver, the educational assistant, or both.

To get some idea of the severity of the problem, it would be best to ask one of the adults on the bus to collect some baseline data. First, it would be necessary to define the problem behavior. Then, if the driver is the consultee, a simple data-collection system will be needed that does not interfere with the job of driving the bus. Hand-held counters or stopwatches can be considered but may be unrealistic in many situations. At a minimum, the driver should be asked to estimate the level of behavior at the end of each trip and record or report it.

For purposes of illustration, the behavior of concern is identified as "name-calling" which typically results in other students on the bus getting angry and name-calling back to the target student. Name-calling is defined as any instance where the student uses a derogatory term to refer to others or others' mothers. In this case, the bus driver would keep track of the number of times the student name-called on each trip. The driver could use a counter to keep track and mark the number of name-calling events on a clipboard at the end of each trip. Baseline data should be collected for a minimum of three days or six trips in order to make some determination about whether there is a pattern. For example, upon inspection of the data, it may be discovered that only afternoon trips are problematic.

Assume the average number of name-calling events was five per trip, and the driver considered this a problem. Several intervention ideas could be considered. From an antecedent point of view, one possible intervention would be to change the student's seat arrangement so that he had to sit in the front row with no other students seated nearby. This might not be effective if the student is quite good at yelling out and attracting peers' attention. However, it might work to assign the student to the front row as a consequence. Thus, a system could be designed whereby the student was required to sit in the front row if the number of name-calling events from the previous trip was more than a prespecified criterion

— five to begin with, and then gradually reduced. The driver would continue to keep track of the number and record them on the clipboard after each trip. If the number of name-calling events decrease, we can assume that the intervention is working.

A more positive approach to improving an individual's bus behavior would be to use some form of a contract. The student and driver could write a contract for the student to earn some type of reward contingent upon improved conduct on the bus. For example, if the target behavior was out-of-seat, the contract could specify that if one or less instances of out-of-seat behavior occur in one week, the student would earn a reward. If the student cannot come up with an acceptable reward to earn, a menu of several items is suggested, some of which are tangible and some of which are activities. The menu might include bubble gum, a soft drink, the privilege of choosing the radio station listened to on the bus, extra free time in class, or a home/bus plan where the student earns the right to stay up an hour later on Friday nights.

If the behavior is of a very high frequency, a weekly reward is probably unrealistic, and a daily reinforcement plan should be considered. Once the behavior is under control, the amount of time to earn a reward could be gradually increased.

Some drivers can handle the contract implementation on their own; however, as in any consultation case, it is best to follow up with the driver by checking daily to make sure that the plan is being implemented as intended and that some other unexpected effects are not occurring. Essentially, if the bus driver is being asked to put in the extra work to implement such a plan, it is best to ensure that he or she experiences success.

Similar individual plans can be developed for behavior problems in the lunchroom or on the playground. Natural consequences work well in these situations; however, one caution is important to mention. Denying a student lunch as a consequence for lunchroom behavior problems is not recommended, is of ethical concern, and considered illegal in many places. Delaying lunch may be appropriate in some circumstances, but the delay should probably be for no more than 30 minutes. As a general rule, it is best not to use lunch as a natural consequence and to assume that lunch is a right extended to all regardless of a student's behavior during the day.

Another variable to consider when designing an individual student program is whether the problem is due to a behavioral excess or a behavioral deficit. If the problem behavior appears to be an example of excess, then the procedures described for changing antecedent and/or consequent events should be helpful. However, if the problem is more of a deficit, that is the student does not have the appropriate skill in his or her repertoire, then a different approach may be more useful. Typically, students with behavioral deficits require direct teaching of prosocial skills. For example, if a student does a lot of pushing and shoving it may be that the student has not learned appropriate ways of gaining peer attention and, thus, resorts to inappropriate means. In such a case, it is necessary to teach the student how to approach peers, how to engage in conversation, and other skills that peers will recognize as positive. Students who exhibit behavioral deficits will require an opportunity to learn and practice prosocial skills. In addition, prompting the student to use a newly acquired skill should help in transferring the skill to everyday situations.

The University of Oregon's Center for Research in the Behavioral Education of the Handicapped (CORBEH) developed a systematic package for teaching socially negative/aggressive children social interaction skills in the playground setting. This package, referred to as RECESS, focuses on teaching a student to discriminate appropriate versus inappropriate social behavior. It utilizes a response-cost procedure, adult praise for positive interactive behavior, and group and individual reinforcement contingencies. The packages developed by CORBEH are very specific, include plans for fading and maintenance, and are recommended to novices who have no previous experience in designing interventions of this type. For general information about the CORBEH packages, please refer to Walker, Hops, and Greenwood (1984) and the annotated bibliography.

CASE STUDY

Staff at a large (750 students) urban elementary school became concerned with the increasing amount of violent behavior that seemed to be occurring in the school. A task force of interested staff formed around this issue and began to discuss the perceived problem in earnest. One of the first things the task force accomplished was to review information the school was already collecting. Suspension data including the reason the student was suspended were compiled. In addition, Quiet Room data were reviewed. In this school, the Quiet Room was a place where teachers could send students if they were being disruptive in the classroom. The Quiet Room also kept data in terms of time of referral, reason for referral, and outcome. Both sets of data collected gave credence to the staff's concern that there was an increasing amount of physically as well as verbally aggressive behavior. In reviewing the data, however, an interesting trend was noted. Many behavior referrals seemed to occur during or immediately after the lunch recess.

The task force met informally once a week for approximately 1 hour and became increasingly more focused on the behavior problems at the lunch recess and their relation to the overall climate in the school being perceived as increasingly violent. This group had a number of goals in mind. A broad goal was to improve the school climate in such a way as to send a message that violence would not be tolerated, and that this school provided a safe and nurturing environment for children. A more specific goal was to develop a lunchroom and recess plan that would increase structure in order to minimize the opportunity for behavior problems.

In examining the current lunch and recess environments, a number of issues became evident. First, it became quite clear that the number of adults assigned to lunch and recess duty was not adequate to provide good supervision. Second, adults assigned to supervise were generally not familiar with the students they were asked to supervise and thus, generally knew few student names. The third thing that was clear upon inspection was that there were no consistent rules for what was acceptable and unacceptable behavior on the playground during recess.

The playground was not ideal in this school and perhaps typical compared to other inner-city schools where space is a premium. Because the playground was bounded by a busy street, it was fenced in. The space itself was about half the size one would prefer and so playground equipment (swings, basketball hoop, etc.) was at a minimum. Worst of all, the children were unable to play games such as soccer requiring a larger than available space. Given that the playground itself was far from ideal, a number of discussions occurred around how to improve the situation. One suggestion was that benches be built for children to sit upon if they chose not to play a game or use the equipment. Currently, the children either sat on the asphalt or leaned against the building. Essentially, the teachers were trying to make what improvements were possible within the given physical constraints of the playground.

The lunchroom/playground supervision was organized in the following way. Teachers were entitled to a duty-free lunch as per their contract. Because they ate at the same time as their students, the lunchroom was usually supervised by one administrator and several educational assistants (paraprofessionals). There were six 15-minute lunch periods with approximately 125 students per lunch. When students were finished eating, they were allowed to go outside to the playground where several more educational assistants supervised. One person monitored the hall route from the lunchroom to the playground. A typical behavior problem scenario looked like this: A student would leave the table without throwing away the milk carton or other trash. A supervisor would call out to the student but, not knowing the child's name, had little impact on getting the student to return to the table. Because there were many other children to watch over, the supervisor would rarely chase after the student and, thus, the student had no consequence for not following the rule of recycling and throwing trash away. The same situation existed on the playground. The educational assistants felt rather powerless to enforce any kind of playground rules and, thus, there was a great deal of running, chasing, and other behavior that easily ended up in fights among students.

The task force set out to change the structure of the lunchroom and playground in order to improve general student behavior and diminish problems occurring in these settings. To do this, several school resources needed to be redeployed which, in turn, required the approval of the entire staff. The first thing requested was round lunch tables rather than the traditional long fold-up tables. Staff believed the round tables would promote the goal of more prosocial behavior at lunch. Second, the entire educational assistant staff for the school was deployed for lunchroom supervision. One assistant was assigned to supervise no more than two classes during lunch. Assistants were asked to make a point of getting to know all the students in their charge early on, and to converse with them during lunch. The educational assistants went to their assigned classroom 15 minutes prior to the student lunch period and took over the class so the teacher could leave and begin his or her own lunch. The purpose of this was to allow the teaching staff a 30-minute duty-free lunch, but one which ended when their students finished eating. The teachers, then, would go to the student lunch room, escort their students to the playground, and supervise the 15-minute recess. This eliminated the need for hall monitors as well as educational assistants on the playground.

In discussing rules for the playground, it was agreed that the primary concern was to enforce existing rules, particularly chasing on the playground — and, thus, games of tag were forbidden. Chasing was viewed as an antecedent to fighting, and by stopping chasing behavior it was hoped that some fighting could be prevented.

Behavioral data from suspensions and the Quiet Room continued to be kept so that comparisons could be made from the previous year. Some remarkable differences were noted. However, the lunch/playground plan alone did not necessarily contribute to the improvement in student behavior, because, in addition to this plan, the school implemented a schoolwide behavior plan with monthly programs to reinforce improved student behavior. Yet it was clear that the number of behavioral incidents during lunch/recess and immediately following were reduced. Initially, some teaching staff were not enthusiastic about having to perform recess supervision, but almost all were converted after they saw the positive effects it had on student behavior. Certainly, some stimulus control effects were evidenced. Most students had relatively good behavior in the classroom setting. By having teachers on the playground, some transfer of behavioral expectations from the classroom to the playground likely occurred.

SUMMARY

Unstructured settings such as school hallways, playground, lunchroom, and the bus typically account for a high percentage of behavior problems that occur in schools. These settings have a number of characteristics in common which likely account for the increased behavioral problems. First, large numbers of children are congregated in one setting, typically larger numbers than in the classroom. Second, the staff-to-student ratio is usually less than what exists in a classroom. These two factors combine to provide less structure than desired, and in the absence of structure, increases in behavior problems can be expected. This chapter provided a number of intervention ideas for these settings. Best practices suggest that antecedents to behavior problems in these settings be considered first. In determining antecedent events, it is possible to identify various aspects of the environment that could be changed or improved to prevent situations from occurring. The second aspect of good practice is being prepared with reasonable consequences for those occasions when behavior problems do arise. Thus, interventions were discussed from both an antecedent and consequent point of view.

This article describes the use of a sound-recording device installed on a school bus. The device was activated when the noise level on the bus was above 500 Hz and a light panel was displayed which provided a visible cue to all the passengers. Students were allowed to listen to appealing music if they could keep the noise level below a specified criterion.

MacPherson, E. M., Candee, B. L., & Hohman, R. J. (1974). A comparison of three methods for eliminating disruptive lunchroom behavior. *Journal of Applied Behavior Analysis, 7*, 287–298.
Part of the tactic described here was for disruptive students to write what is described as a mediation essay. These students during their lunchroom timeout had to respond in writing to questions such as "What did I do wrong?" and "What should I have done?" Some written language teachers object to using writing as a punishment; however, this same tactic could be used but change the consequence to loss of recess or some other potentially motivating variable.

Murphy, H. A., Hutchison, J. M., & Bailey, J. S. (1983). Behavioral school psychology goes outdoors: The effect of organized games on playground aggression. *Journal of Applied Behavior Analysis, 16*, 29–35.
The conclusion reached by the authors was that when dealing with large groups, manipulating antecedent events may be more practical than trying to provide consequences. Thus, organized activities such as rope-skipping and foot races were implemented as a means of attending to antecedent events. Natural consequences were provided to students who did not follow the activity rules.

Best Practices in the Response to Child Maltreatment

Connie Burrows Horton
Illinois State University

> The child trapped in an abusive environment is faced with formidable tasks of adaptation. She must find a way to preserve a sense of trust in people who are untrustworthy, safety in a situation that is unsafe, control in a situation that is terrifyingly unpredictable, power in a situation of helplessness.
>
> Herman, 1992, p. 96

OVERVIEW

Given the nearly impossible tasks for abused children described above, the roles for school psychologists endeavoring to support the development and recovery of child victims may also be overwhelming. Yet school psychologists are increasingly being identified as among the critical respondents to the tragic phenomenon of child maltreatment. It is imperative, therefore, that all school psychologists maintain a basic level of awareness of issues regarding child abuse and neglect, so that they are prepared for identification, reporting, referring, and consulting roles. Others may choose to specialize in additional roles involving direct intervention and prevention activities. Thus, the purpose of this chapter is twofold: (a) to provide a brief summary of issues and roles that almost all school psychologists should be prepared to address, and (b) to provide a springboard from which those wishing to specialize may begin.

The maltreatment of children is currently recognized as a social problem of major proportion (Gil, 1980). National incidence studies, using conservative estimates of countable reported cases, reveal that more than 1.5 million children nationwide are victims of abuse or neglect each year (NCCAN, 1988). Given that many children do not report their abuse but attempt to protect parents and cover up injuries (Broadhurst, 1980), reported cases should always be viewed as gross underestimates of the actual number of abused children. Thus, even these "tip of the iceberg" statistics demonstrate the epidemic proportions of this national tragedy. Clearly, for many children, the family home is a dangerous place (Kolko, 1992). Given the now recognized increased vulnerability of children who have experienced maltreatment to immediate physical pain and emotional distress as well as long-term risks of delinquency, psychiatric disorders, school failure, self-destructive behavior, domestic violence, and sexual dysfunction — the costs to individuals, families, and society are increasingly being recognized as overwhelming (Garbarino, 1983).

While the maltreatment of children has been occurring for centuries (Garbarino, 1977), public acknowledgment of this tragedy is very recent. One might expect that the medical community would have recognized child abuse long ago, considering the many suspicious injuries physicians have treated. However, the medical field, too, responded slowly (Gil, 1991). Though there were a few physicians who raised questions about child abuse earlier, it was not until 1961 when Kempe coined the phrase "the battered child syndrome" at a medical conference presentation and published his findings, that the medical field considered the problem seriously (Kempe & Helfer, 1980). The passage of laws between 1963 and 1965 that required medical reporting of abuse led to the establishment of child protective agencies. In 1974 the Child Abuse Prevention and Treatment Act became law. This act established a National Center on Child Abuse and Neglect that has been involved in public education, the support of improved child protective services, and research to improve identification, prevention, and treatment of child maltreatment (Green, 1980).

By the 1980s, schools were recognized as potential resources in the response to child maltreatment. "As the major institution concerned with the development of children it seems natural that schools should assume a major responsibility in facilitating, reporting, and participating in the delivery of services to the abused" (Volpe, 1980, p. 3). Since school personnel operate under legal and ethical mandates, and the opportunity for abuse to be detected, identified, and reported exists in the school settings, it does seem appropriate to expect school professionals to be involved.

School psychologists, in particular, have been identified as having the position and expertise that uniquely enables them to respond to various forms of child maltreatment (Erickson & Egeland, 1987; Garbarino, 1987; Gelardo & Sanford, 1987; Tharinger, Russian, & Robinson, 1989; Vevier & Tharinger, 1986). Given their skills in communicating with children and adults who may have relevant information, their knowledge of child and family function and dysfunction, and their training in assessment, interviewing, and consultation, and given the perception by others that they are helpers and problem solvers (Vevier & Tharinger, 1986), the expectations that school psychologists will be leaders in the schools' response to child maltreatment seem reasonable.

BASIC CONSIDERATIONS

School psychologists must have a working knowledge of child maltreatment issues so that they are in a position to respond appropriately (Vevier & Tharinger, 1986). It is important to have a basic understanding about why child maltreatment occurs, as well as an awareness of issues regarding each form of abuse. Thus, the following is a brief review of models used to explain the phenomenon of abuse and a discussion of the four major types of child maltreatment: physical abuse, sexual abuse, neglect, and emotional abuse.

Models

Various models, including psychiatric (focusing on individual pathology of offenders), sociological (focusing on societal factors such as unemployment), and family systems (focusing on the function of abuse within the family) have been proposed to explain the occurrence of child maltreatment (see Gelardo & Sanford, 1987; Vevier & Tharinger, 1986). Increasingly, researchers and clinicians are recognizing that each of these models is too simplistic. More complex, ecological models that recognize the interplay between factors are needed to explain abuse (Garbarino & Gilliam, 1990). Ecological models acknowledge the contributions of the individual, family, community, and culture that contribute to the occurrence of child maltreatment (Belsky, 1980). Thus, school psychologists are reminded that causes are complex and that once they have an understanding of abuse issues, their response can be multifaceted.

Physical Abuse

Description. The physical abuse of children may take many forms and vary in both severity and duration. For example, some children are injured during extended physical altercations (e.g., hitting, kicking), others are physically harmed in brief, isolated incidents (e.g., being burned, or thrown down stairs). Additionally, there are many other children who may not meet legal definitions of physical abuse but suffer harsh physical discipline (Kolko, 1992). While the majority of abuse cases cause moderate injuries (those that persist in observable form for 48 hours or more but are not life-threatening), over 1,000 children die annually at the hands of their abusers (NCCAN, 1988).

Incidence. The exact scope of the occurrence of physical abuse is unknown because of unreliable data, variety of sources, and variance in definitions (Gelardo & Sanford, 1987); however, conservative estimates reveal that over 350,000 children are physically abused annually (NCCAN, 1988). Male and female children seem equally at risk for this type of abuse, and while older children are more likely to be physically abused, very young children are more likely to suffer severe, even fatal, injuries (NCCAN, 1988).

Effects. Physical abuse affects a child in many ways. Direct physical injuries are perhaps the most obvious effects of this form of child maltreatment. Such injuries may include skin injury (such as bruises, welts, abrasions, puncture wounds, burns, and scaldings), skeletal injury (such as skull and bone fractures and dislocations), and internal injuries (such as brain damage or internal organ damage) (Gelardo & Sanford, 1987).

Psychological effects are also varied. While teachers are most aware of externalizing symptoms (Haskett & Kistner, 1991), internalizing symptmology is also often present. Internalizing symptoms that are commonly found among physically abused children include a lack of positive affect (Erickson & Egeland, 1987), withdrawal (Haskett & Kistner, 1991), depression (Kolko, 1992), and low self-esteem (Gelardo & Sanford, 1987). Externalizing symptoms include noncompliance (Erickson & Egeland, 1987), and instrumental aggression, even at young ages (Haskett & Kistner, 1991). Clearly, not all children who are physically abused will become aggressive. Just as in other pathologies, there may be a temperamental or genetic predisposition toward aggression or resiliency. However, living with aggressive adult models and experiencing physical assaults at the hands of one's parents greatly increases the odds that a child will become aggressive (Lewis, 1992). The aggressive tendencies may develop into more serious conduct problems in adolescence, including fighting, property offenses, other delinquent activities leading to arrests, and higher rates of alcohol and drug use (Kolko, 1992).

Given these symptom patterns, it is not surprising that children who have been physically abused are generally not popular among their peers (Erickson & Egeland, 1987). In fact, the social/peer domain is perhaps the most affected area for physically abused children (Kolko, 1992). Their interactions with familiar peers are markedly different from nonabused children's and tend to be marked by both withdrawal and aggression (Haskett & Kistner, 1991). They may exhibit a number of social skills deficits (Gelardo & Sanford, 1987). For example, children who have been the victims of physical abuse often show difficulty reacting appropriately to positive peer initiation. Furthermore, they often appear unable to respond supportively to peer distress, perhaps because of difficulty empathizing (Kolko, 1992). Therefore, even at very young ages, peers find children who have been abused to be less desirable playmates; thus, the abused child continues to be at risk for peer rejection (Haskett & Kistner, 1991).

Of particular note to school psychologists are the multiple academic problems that children who have been abused frequently experience, including poor school achievement, failing grades, and increased risk for retention or referrals for special education services (Erickson & Egeland, 1987; Gelardo & Sanford, 1987). There are multiple explanations for such academic difficulties. Clearly, emotional factors are critical considerations. It is difficult for a child to learn who is withdrawn, depressed, and having difficulty concentrating because of distress regarding recent abuse or fears of potential future abuse. Alternative or additional explanations may also apply. For example, if physical abuse involves head injuries, intellectual impairment may be a direct consequence (Gelardo & Sanford, 1987). Further, the academic careers of maltreated children are often marked by considerable discontinuity, because of frequent moves, school transfers, and tardiness (Kolko, 1992). Additionally, these children have also been noted to be disruptive, inattentive, and impatient in the classroom (Erickson & Egeland, 1987). In later years, abused children continue to have disciplinary problems at school and thus have higher rates of suspensions (Gelardo & Sanford, 1987). It is apparent that the school psychologist should consider multiple explanations for academic difficulties experienced by students who have been physically abused.

Sexual Abuse

Description. Sexual abuse has been defined as "the involvement of dependent, developmentally immature children in sexual activities that they do not fully comprehend and therefore to which they are unable to give informed consent and/or which violate the taboos of society" (Krugman & Jones, 1987, p. 286). Sexual abuse is not limited to sexual intercourse. Sexual assaults involving adult sexual contact with children may include fondling of breasts and genitals, oral sex, anal penetration, and vaginal intercourse. Additionally, some forms of child sexual abuse do not involve actual sexual contact with offenders. Examples of such noncontact abuse include encounters with exhibitionists, solicitation to engage in sexual activity when no physical contact occurs, and exposure to or involvement in pornography (Courtois, 1993; Peters, Wyatt, & Finkelhor, 1986). It is common for sexual abuse to progress from less to more invasive forms. For example, an offender may expose himself to a child, then move to fondling, oral sex, and then intercourse (Courtois, 1993).

Offenders may gain access to a child victim through deception or by direct approach through the use of psychological pressure, enticement, and encouragement. In some cases force, threats, or use of strength are involved (Burgess & Groth, 1980). Thus, a child victim will keep the secret of sexual abuse for a variety of complex reasons, which may include being deceived into thinking the experience is normal or educative, because she fears for her life or the life of her family, or because she gets some "benefits" or "payment" for participating.

The majority of sexual offenders are family members or those known to the child (Finkelhor, Hotaling, Lewis, & Smith, 1990). Males are apparently more likely to be sexually abused by someone outside of the family, whereas females are more likely to be sexually abused by someone within the family (Courtois, 1993). The vast majority of sexual abuse is perpetrated by males, though there are some cases in which females victimize male or female children (Finkelhor et al., 1990).

Incidence. Incidence and prevalence figures for this type of abuse vary widely depending on the source of the information, the definitions of abuse included, and the population studied (Vevier & Tharinger, 1986). Very conservative estimates suggest that over 150,000 new cases of child sexual abuse occur annually (NCCAN, 1988); underreporting of this type of abuse, however, has been characterized as "massive" (Kempe, 1980).

Retrospective studies of adults reporting on their childhood histories reveal alarming rates of sexual abuse. For example, a recent national survey of child sexual abuse found victimization reported by 27% of women and 16% of men (Finkelhor et al., 1990). While the ratio varies depending on the study, females appear to be at greater risk than males of becoming victims of sexual abuse, though most observers acknowledge that the abuse of boys is still significantly underreported (Finkelhor & Baron, 1986). While reported cases are approximately 5 females for every one male victim reported, retrospective studies find that an average of 2.5 females report a child sexual abuse experience for every male who reports victimization (Finkelhor & Baron, 1986).

Almost all studies report that children are most vulnerable to sexual abuse starting between the ages of 8 and 12 years (Finkelhor & Baron, 1986), though in some cases the abuse starts at much younger ages, even in infancy. The average length of intrafamilial sexual abuse is 4 years, while extrafamilial abuse is generally much shorter in length, probably owing to more limited access to the child victim (Courtois, 1993).

Effects. Because of the range of responses of victims of child sexual abuse, it is difficult to postulate a "post-sexual-abuse syndrome" with a specific course or outcome (Beitchman, Zucker, Hood, DaCosta, & Akman, 1991). While individual responses vary, there are a number of common symptoms found among child victims of sexual abuse.

Child victims of sexual abuse may suffer any number of physical effects, including bladder injuries, rectal and vaginal tears or bruising, lacerations on genitalia, and sexually transmitted diseases (Bates, 1980; Brassard, Tyler, & Kehle, 1983) and pregnancy. Child victims may experience a variety of somatic complaints (e.g., headaches, stomachaches), and sleep difficulties including insomnia and night terrors are also common (Vevier & Tharinger, 1986).

Emotionally, child victims of sexual abuse may initially experience fear, anxiety, depression, anger, or hostility (Browne & Finkelhor, 1986). Some observers have referred to the "sleeper" effect, describing many children who do not experience significant pathology until late adolescence or adulthood, at which point survivors are more likely to manifest depression, self-destructive behavior, anxiety, feelings of isolation and stigma, poor self-esteem, a tendency to experience further victimization, and substance abuse (Browne & Finkelhor, 1986).

Behaviorally, child victims of sexual abuse often regress and may engage in thumb-sucking, bedwetting, or other behaviors typical of younger children. Many sexually abused children internalize their distress and will be cooperative or overly compliant. Other victims, especially if they attempted to get help but were ignored, may act out their anger through a variety of behaviors (Vevier & Tharinger, 1986). Additionally, adolescents may engage in delinquent or runaway behaviors, play a parental role in the family, or exhibit suicidal behavior (Brassard et al., 1983).

School difficulties are also common among child victims of sexual abuse. Academic achievement often declines, apparently partially because of an inability to concentrate (Vevier & Tharinger, 1986). Grades also suffer from what may appear to be a rebellious attitude (e.g., refusal to change for gym class). Additionally, children who were developmentally delayed before the abuse, and thus were more vulnerable to being victimized (Tharinger, Horton, & Millea, 1990), may further deteriorate academically following the abuse (Beitchman et al., 1991).

Socially, victims of sexual abuse often have difficulties (Brassard et al., 1983). While children who have been sexually abused may not be as aggressive as their physically abused counterparts, they still tend to have inadequate peer relationships. These children often demonstrate an inability to make friends (Vevier & Tharinger, 1986). Thus, they become extremely dependent on adults (Erickson & Egeland, 1987) and may be excessively clingy and demonstrate a need for an unusual degree of reassurance (Brassard et al., 1983).

Finally, victims of sexual abuse may develop fear and anxiety regarding the opposite sex or sexual issues (Brassard et al., 1983) and may display inappropriate sexual behavior (Browne & Finkelhor, 1986). In young children, this tendency may be observed in heightened interest in, or a preoccupation with, sexuality that may be manifested in a number of ways including sexual play, excessive masturbation, sexually aggressive behavior, and age-inappropriate sexual knowledge. Adolescent sexual difficulties include sexual dissatisfaction, promiscuity, and an increased risk of further victimization (Beitchman et al., 1991).

Neglect

Description. The dynamics involved in situations of child neglect are significantly different than those involved in situations of physical or sexual abuse. Perhaps the greatest difference is that abused children receive attention (Gil, 1991). While it is true that the attention is negative and potentially very damaging, the child's presence is acknowledged. This is often not true for neglected children, who are often treated as if they do not exist. Neglect is more subtle, but it can cause irreparable damage (Bates, 1980).

Neglect has been defined as "a form of maltreatment characterized by a chronic lack of care in the areas of health, cleanliness, diet, supervision, education, or meeting of emotional needs that places the child's normal development at risk" (Ethier, Placio-Quintin, & Jourdan-Ionescu, 1992, p. 13). Since, by definition, neglect involves absence, definitions are complex and vague (Ethier et al., 1992). Although states may try to clarify some specifics such as at what age a child may be left unsupervised, it is difficult to define the point at which a child slips from satisfactory care to neglect (Helfer, 1987).

Neglect may be chronic or circumstantial (Ethier et al., 1992). Chronic situations may include a wide variety of situations such as intellectual handicap, drug abuse, or emotional immaturity on the part of parents (Ethier et al., 1992). It is important to note that while neglect may be more easily detected among poor families because, in those cases, there is more likely to be inappropriate dress, evidence of malnutrition, and the like, emotional neglect occurs across all socioeconomic groups.

National incidence studies conducted by the National Center for Child Abuse and Neglect include three types of neglect: physical, emotional, and educational. The definition of physical neglect includes the refusal or delay of health care, abandonment, and inadequate supervision. Emotional neglect includes inadequate nurturance/affection, chronic or extreme spouse abuse, permitted drug or alcohol abuse, other permitted maladaptive behavior, and refusal or delay of psychological care. Educational neglect includes permitted chronic truancy, failure to enroll, and inattention to special educational needs.

Incidence. Partially as a result of definitional complexities, and the ease with which some forms may be hidden, it is difficult to determine with any accuracy the incidence and prevalence of neglect (Ethier et al., 1992). Incidence studies conducted by the National Center for Child Abuse and Neglect report over one million cases of neglect annually (NCCAN, 1988). Physical neglect is the most documented form of neglect, accounting for 57% of the reported cases. Educational neglect accounted for 29% of the total of neglect cases, while emotional abuse accounted for 22% of the total cases of reported neglect.

Effects. Children who are victims of neglect often exhibit poor weight gain, delayed developmental growth, and varying degrees of malnutrition (Cantwell, 1980; Helfer, 1987). These children often suffer from frequent illness. While the illness may not be serious, they are often chronic (Helfer, 1987). The "failure to thrive" syndrome (i.e., failure over time to grow to accepted standards for height, weight, and development) has been used to describe children who have been neglected (Helfer, 1987).

Emotionally, children who have been neglected appear to be anxious and withdrawn, and they may repress their other feelings (Polansky, 1981). Such repression is understandable. If no one appears to be available to comfort, support, and protect, a child learns to silence feelings of aloneness, fear, or anger. Self-esteem, a fundamental basic to mental health, is of course greatly compromised.

Socially, the effects of neglect include disrupted attachment and an impaired ability to empathize with others. The latter can lead to violence and delinquency (Polansky, 1981). Some have suggested that the social competence of children who have been neglected is, as a result of a lack of experience, lower than that of children who have experienced physical or sexual abuse (Erickson & Egeland, 1987).

Children who have been neglected often have a very difficult time performing adequately in academic settings. At even very young ages, these children may exhibit developmental delays, especially in language (Cantwell, 1980), that continue to plague them in school. In fact, the academic skills of children who have been neglected are often lower than those of children who have experienced other forms of child maltreatment. One reason for academic difficulties may be that the psychologically unavailable parent does not provide the encouragement, participation, and responsiveness to school activities and achievements required for success (Helfer, 1987).

Emotional Abuse

Description. Emotional abuse includes treating a child in a way that is rejecting, degrading, terrorizing, isolating, corrupting, or exploiting, or that denies emotional responsiveness (Brassard & Gelardo, 1987). Some prefer to use the term *psychological maltreatment* rather than emotional abuse, since this type of maltreatment of children affects more than emotions and clearly has both cognitive and affective components. In some ways, definitions of emotional abuse are more vague than other types of abuse. That is, it is difficult to know where to draw the line and say that particular parental behavior is truly emotionally abusive. At the same time, this form of abuse relates to the core issues that are inherent in all forms of child maltreatment, and thus clarifies and unifies constructs (Brassard & Gelardo, 1987). That is, a child who is physically abused is clearly also emotionally abused. Likewise, a child who is sexually abused or is neglected is also affected emotionally and psychologically. Still, emotional abuse can occur in isolation. It is possible for a parent never to be physically violent, never cross sexual boundaries, and continually provide adequate nutrition, education, and supervision, and still be emotionally abusive, by making constant, degrading, hurtful comments.

Incidence. Since definitions are so unclear, many states do not keep records of emotional abuse (Gelardo & Sanford, 1987). However, approximately 211,000 cases of emotional abuse are reported annually (NCCAN, 1988). It should be noted, however, that reported cases generally include only extreme situations such as tortuous restriction of movement (e.g., tying a child to a bed), threats of abandonment, or attempted but not completed physical or sexual abuse. The more subtle forms of emotional abuse such as rejecting, degrading, or not responding to children are generally not detected or not reported.

Effects. Some have argued that the psychological effects that result from emotional abuse are the most long lasting (Brassard & Gelardo, 1987). Generally, physical injuries from abuse heal; however, deep psychological wounds are more persistent. In fact, it is possible that it is even more difficult for emotional abuse to heal when there are no physical injuries, experiences of neglect, or memories of sexual assaults. The lack of evidence of injury may confuse victims about the severity of their abuse. For example, although shouting and threatening might have completely terrorized a child (Ethier et al., 1992), the child (or adult survivor) has no proof of injury. Although she may feel horrible, she may be unable to identify that the feelings are the result of someone else's abusive behavior.

In sum, children who are emotionally abused feel abused, unwanted, angry, and bad (Bates, 1980). Psychological abuse has been demonstrated to be a critical variable in predicting levels of depressions, self-esteem, and attributional style. Children subjected to this form of abuse have not had important psychological needs met by significant adults and are affected accordingly (Brassard & Gelardo, 1987).

In addition to the emotional effects, psychological maltreatment is a threat to social competence. Being treated in an emotionally abusive manner distorts a child's concepts of social relationships, creates socially dysfunctional defenses, and elicits patterns of inappropriate behavior (Gross & Keller, 1992).

Overall Effects

As is evident from the description of emotional abuse, the various forms of maltreatment of children often do not occur in isolation. That is, abuse or neglect of one type often occurs simultaneously with other types of maltreatment. Furthermore, while specific types of abuse produce certain unique injuries and effects, there appear to be certain shared effects among various forms of maltreatment as well (Briere, 1992). Therefore, while it is important to consider various forms of abuse and neglect separately, it may also be beneficial to examine them in summary form.

In short, child victims of abuse tend to develop internalized symptom patterns that reflect an attempt "to negotiate the trauma themselves" or externalized behaviors in which the symptoms are directed toward others (Gil, 1991). Commonly noted internalizing symptoms among victims of child abuse include withdrawal, depression, a lack of spontaneity and playfulness, overcompliance, phobias, hypervigilance/anxiety, sleep disorders or night terrors, regressed behavior, somatic complaints, eating disorders, substance abuse, suicide gestures, self-mutilation, and dissociation. Externalized symptom patterns that are commonly found among abused children include behavior that is aggressive, destructive,, provocative (eliciting abuse), violent, or sexualized. Specific behaviors such as fire setting and killing or torturing animals are also seen among some abused children (Gil, 1991).

Mediators of Effects

The effects discussed above are findings from group studies and are common findings among clinicians. It should be acknowledged, however, that not all child victims experience the same symptoms or the same severity of symptom patterns. There are a variety of factors that mediate the impact of child abuse, including the following: the age of the child at the time of the abuse, chronicity of the abuse, severity of the abuse, the relationship with the offender, the level of threat involved, the emotional climate of the family prior to the abuse, the child's emotional/mental health functioning prior to the abuse, the amount of guilt that the child feels, the sex of the victim, and parental response (Gil, 1991).

Another important mediator for school psychologists to consider is the response of significant others, including schools, towards the child victim and toward the offender (Hindman, 1989). Child victims who find that significant people in their lives believe and support them and clearly place the responsibility for the abuse with the offender are likely to experience less trauma. In a disturbing case example, Hindman (1989) reports a situation in which a male sixth-grade teacher sexually abused several children. The school personnel did not respond in a way that was supportive and affirming of the victims. Instead, the children were pulled out of classes, confronted by other teachers about their claims, and were allowed to be interviewed by the offender. At the same time, school personnel had a car wash and a baked food sale on school grounds to raise money for the teacher's legal defense: These responses had a tremendously negative effect on the boys: Two dropped out and one committed suicide (Hindman, 1989). Clearly this is an extreme example; however, it should remind school personnel that their response to the abuse of a child may make a positive difference that promotes that child's recovery or may be the last straw for a child who has experienced far too much maltreatment.

BEST PRACTICES

In considering the appropriate response and roles for school psychologists, an intervention framework, proposed for response to sexual abuse (Vevier & Tharinger, 1986), may be generalized to apply to response to all forms of child maltreatment. This model consists of two levels: one that incorporates roles for all school psychologists and another that particularizes roles for those wishing to specialize in working with these children.

General Roles

Detecting abuse. School personnel, including school psychologists, have been recognized as key respondents to child maltreatment, partially because they have the opportunity to detect child abuse in their work. Unfortunately, schools have not responded well to the tragedy of abuse. This is largely the case because school personnel do not recognize indicators of abuse and neglect (Broadhurst, 1980).

Commonly observed symptoms of maltreatment such as those discussed above, while not conclusive in isolation, are indicators of possible abuse (Gil, 1991) that school psychologists should consider. Awareness of the symptoms and prevalence of abuse allow school psychologists to consider abuse as a possible cause of some behaviors. For example, when a child is referred for an assessment because of his poor academic performance, does the school psychologist consider whether the child has eaten before coming to school? When an adolescent female is suspended for refusing to dress down for P.E., does the school psychologist consider that she may be experiencing shame and discomfort regarding her body following episodes of sexual abuse? When a kindergarten boy is extremely aggressive, does the school psychologist wonder about where he learned that behavior or what is behind the anger before developing a behavior modification plan? When a child is referred for suspected Attention Deficit Disorder in view of an inability to concentrate, does the school psychologist wonder about what possible distraction the child is concentrating on or working hard to forget? Clearly, school psychologists should not make conclusions about child maltreatment with only limited descriptions of symptoms, but they can use child maltreatment, along with other possible explanations, as a possible initial hypothesis in the assessment process. Once again, lists of effects of abuse are not conclusive in themselves but should be reminders of possible explanations for a child's behavior, affect, or school performance.

In recognizing indicators, school psychologists will need to work closely with other school personnel. For example, a school nurse might be the first to be aware of difficulty in walking or sitting; torn, stained, or bloody underclothing; complaints of pain or itching in the genital area; bruises or bleeding in external genital, vaginal, or anal areas; or veneral disease in cases of sexual abuse (Brassard et al., 1983). Teachers may be the first to recognize aggressive or withdrawn behavior as well as bruises or other injuries in children who have been physically abused. Thus, ongoing collaborative communication between school professionals is critical if child abuse is to be accurately detected.

School psychologists should be reminded to notice not only difficult, acting out, or overtly disturbed students. In addition, there should be equal concern for uncommunicative children, who are little trouble to their teachers but may be seriously depressed by abuse, neglect, or some other difficult home situation (Fewster & Bagley, 1986).

Child interviews. Often a school psychologist may have concerns regarding possible child maltreatment because of physical, emotional, or behavioral indicators but may need additional information. In other cases, a child may make a direct disclosure regarding abuse to the school psychologist or other school professional. In either of these situations, the school psychologist, if she or he has the skills to do so, may need to interview the child further to gain enough information to make a report (Brassard et al., 1983).

The school psychologist, whether following up on indicators of abuse (Brassard, et al., 1983) or responding to a child's disclosure (Johnson, 1989), should be careful to conduct a clinically sensitive, yet legally defensible, nonleading interview. The most important aspect of a child interview may be a warm, caring, nonjudgmental style. Although variations in individual style are acceptable (Johnson, 1989), some key points are important for all to consider.

First, the school psychologist must be clear about limits to confidentiality. Sometimes without mentioning anything about abuse, children will attempt to get school professionals to make promises of absolute confidentiality (e.g., "If I tell you something very, very private, will you promise not to tell?"). School psychologists are reminded not to naively agree, but to be clear with a child (in developmentally appropriate terms) about limits to confidentiality. A frank discussion regarding confidentiality at the outset may prevent a child from disclosing abuse at that time. However, upon further consideration, the child may appreciate the honesty, realize this is an adult who can be trusted, and disclose at a later date. In either case, being honest with a child is preferred to having to betray the child's trust by breaking a promise that never should have been made.

Interviews regarding suspected child maltreatment should be conducted in a private setting. Given the shame, embarrassment, and confusion that victims of abuse experience, the school psychologist must be especially sensitive to issues of privacy. While practical constraints may exist, it is imperative that the school psychologist find some place in the school where he or she can be alone with the child rather than using a corner of a classroom or an open space in a hallway where other students or school personnel may overhear the conversation. A child victim may be more likely to deny the abuse if he or she fears others may be listening to the conversation.

The school psychologist should maintain a somewhat informal, calm tone throughout the interview. Rather than immediately grabbing a clipboard to take notes, the school psychologist should more informally dialog with the child, starting with more general, nonthreatening subjects, and leading up to topics related to the suspected abuse. Once the child does begin discussing the abuse, it is important that the school psychologist remain calm. The interviewer should be careful not to alarm the child through the display of reactions of extreme disgust, horror, or shock. Often a child will tell about a limited aspect of the abuse experience initially, as if to test the interviewer. A child who concludes that the interviewer "can't handle it" may not go on to tell what else happened.

Basic, good listening and child-oriented communication skills are imperative throughout the interview. The school psychologist should listen carefully to what the child is saying, while at the same time, noticing nonverbal communication. The interviewer should work to use developmentally appropriate language and concepts, noticing and using the child's words. Open-ended questions that facilitate disclosure are preferable to closed-ended questions that can be answered yes or no and may lead the child or interrupt the child's story (Krugman & Jones, 1987). Thus, questions like "What happened next?" are generally better than "Then did he hit you?" More focused questions may be appropriate at the end of the interview to clarify information (e.g., "Do you know your Uncle John's last name?").

As with any sensitive clinical work, the school psychologist should listen and validate how the child feels rather than guessing or telling them how they must feel. Given the wide variety of abuse experiences children have suffered and the various stages of feeling that each child may go through, the school psychologist really cannot assume what the child feels. Thus, comments like "I'm sure you feel guilty, but you shouldn't" or "I know you're angry. You have a right to be," while well-intended, are generally not helpful.

Keeping in mind that children rarely lie about abuse and that it is important only to get enough information to make a report since others will do a more investigative interview to determine the accuracy of statements, school psychologists should generally assume a child is telling the truth and act accordingly. Direct or subtle messages of disbelief may squelch the child's further disclosure. Instead, the child should be reassured that telling someone was the right thing to do.

At the conclusion of the interview, it is important for the school psychologist to explain, as much as possible, what will happen next. For example, if the child has disclosed abuse, the school psychologist should inform the child that the abuse will be reported and what can be expected to happen. While the school psychologist clearly will not be able to say definitively how a child protection agency will proceed, a good working relationship with such agencies allows school psychologists to have some idea of the likely response for various types of abuse reports. The school psychologist might be able to tell an adolescent who has suffered mild physical abuse, "A social worker may call your parents and ask what has been going on or to suggest a counselor." On the other hand, a school psychologist might warn a young sexual abuse victim, "The policy may come to school to talk to you. That does not mean you are in trouble. They will be trying to help you." Another aspect of informing a child about what to anticipate next is to be clear with the child about what to expect from the school psychologist. It is important to be honest with oneself and with the child. As well-intended, caring people who are deeply concerned about child victims, some school psychologists may be tempted to volunteer for more than they can really do. A realistic explanation of "I'll be checking in with you every week or so, and you can ask your teacher to contact me in an emergency" may be more honest than "I'll stick with you through this whole thing. I'll go to court. I'll be with you wherever you go, whatever you need." Since most school psychologists are overburdened with multiple demands, clear boundaries are better for everyone concerned.

When the interview is completed, the interviewer should document the conversation in as much detail as possible. Without being obtrusive or overly formal, some school psychologists prefer to jot brief notes, including key phrases used by the child, during the interview and fill in extra details after the interview. Others, depending on state and district regulations, tape record the interview and take notes while listening to the tape. The child should be informed accordingly.

Given the importance and complexity of this work, whenever possible, school personnel should allow trained personnel from an abuse agency to handle the interviews (Brassard et al., 1983). School psychologists should conduct interviews only to gain information to make the report and thus involve abuse experts.

Reporting abuse. Once there is enough information from physical, behavioral, or emotional indicators, and/or child reports to suspect abuse, a school psychologist, as a mandated reporter, must draw up a report to the appropriate child protective agency. School psychologists should be familiar with the laws on reporting child abuse in their state (Brassard et al., 1983), since the specifics — such as which agency should be contacted, and the time frame within which the written report that follows the immediate oral report must be made — vary from state to state.

Certain important aspects are consistent across states, however. For example, school psychologists are generally mandated reporters, so the failure to report is considered a class B misdemeanor as a negligent party (Brassard et al., 1983). Further, no state requires proof of abuse, but rather only a "reason to suspect" (or some similar phrase) before a report is required. Thus, school psychologists are warned not to wait until they have irrefutable evidence. In fact, every state provides immunity from civil liability and/or criminal penalty for those who do report abuse, provided the report is made in good faith (Brassard et al., 1983).

While mandated to report, many professionals are reluctant to do so for a variety of reasons (Johnson, 1989). For example, many are afraid of testifying or getting involved because of potential physical or legal retribution. Others are reluctant to report because they do not trust the protective agency to respond appropriately. Thus, they fear there will be no enforcement, but just enough agency involvement to get the child in further trouble, or an overreaction by the system that will end in having the child pulled from secure, positive experiences, such as school, as a consequence of an out-of-home placement (Johnson, 1989). In sum, there is a fear that reporting will retraumatize the child.

Given the countless tragic cases nationally that have been handled inappropriately, such fears may be justified. On the other hand, school psychologists must keep the larger picture in mind. It is through public disclosure of child maltreatment and the involvement of social agencies that the abusive cycle can be broken and the healing cycle may begin (Johnson, 1989). Furthermore, while there may be some risks in reporting, there are also many risks, both legal and ethical, for not reporting suspected abuse. Imagine, for example, a case in which a school psychologist does not report the suspected physical abuse of a child because of some of the fears discussed above, and later the child is more severely injured or killed.

In addition to making their own difficult reporting decisions, school psychologists may find themselves in positions of advising others on reporting dilemmas. Within schools, teachers are most likely to suspect maltreatment and initiate child abuse reports; however, in many schools principals act as gatekeeper. In this common practice, teachers and other school personnel are asked to discuss suspected abuse with the principal, who will then decide whether to make the report (Zellman, 1990). Since some states require direct reports from the person who suspected abuse, the gatekeeper role, especially if the principal does not report situations that others believe are reportable, may not meet legal requirements. School psychologists may be in positions to consult, advise, or mediate in such situations. Furthermore, a school psychologist who keeps abreast of current legal requirements in the state may offer inservice training for both administrators and teachers (Brassard et al., 1983). State law and district policy should be examined to ensure congruence. Generally, however, school principals are good reporters who may need some additional support from school psychologists regarding difficult situations (Zellman, 1990).

Consultation with teachers. In addition to training and consultation regarding reporting decisions, teachers may appreciate the school psychologist's input regarding other aspects of dealing with a child victim. Abused children often need and can benefit greatly from a special attachment with a concerned teacher (Gelardo & Sanford, 1987), especially if they are able to spend the majority of the school day with one special teacher (Erickson & Egeland, 1987). At the same time, given the multiple symptom patterns described above, it is not always easy for a teacher to maintain a positive relationship with an abused child.

Although the awareness and sensitivity of teachers to the problem of child maltreatment is growing, many will still find it difficult to act upon their concerns. When children who have been maltreated act out in class, teachers find the situations to be upsetting emotionally (Milgram, 1984) and challenging to the classroom structure and routine. Teachers need support and encouragement for their persistent efforts to be patient and understanding of children who have been abused. School psychologists may assist by helping to reinterpret a child's behavior to a teacher, thus helping the teacher to avoid a classroom replication of the child's destructive family relationships (Erickson & Egeland, 1987). Behavioral and mental health consultation may be appropriate. In cases of sexually reactive children, teachers may need very specific suggestions and guidelines regarding supervision and appropriate interventions (Slater & Gallagher, 1989).

While the child's privacy must be respected, teachers sometimes need some information to respond sensitively to children who have been maltreated. The school classroom may be the most stable setting these children experience, and teachers may provide the empathy and positive regard needed to help children cope with their ordeal (Gerler, 1991). Thus, while maintaining professional standards of confidentiality, a school psychologist may elect to share some general information with a teacher who may have a need to know, so that the teacher can respond appropriately and supportively. Allowing the child the opportunity to be with one teacher who knows him or her well may increase the likelihood of promoting that child's adjustment (Erickson & Egeland, 1987).

Consultation with parents. School professionals may want to avoid contact with families once abuse has been reported. However, that response may be detrimental to the child. Supporting the families, even in the most difficult times, is a way of supporting children. School psychologists are urged to promote positive relationships between the child and caretaking parents.

Specifically, school psychologists must do what they can to support the positive mental health of caretaking parents. It is important to remember that most parents, even abusive ones, want to be good parents. Parents who may be stressed, overburdened, or ill-equipped for their roles, deserve caring, nonjudgmental support, just as children deserve protection when necessary (Gelardo & Sanford, 1987). School psychologists are advised to report what they need to report, but then let the legal and protective agencies handle prosecution decisions. Parents, even those believed to be abusive, should still be treated with respect.

Additionally, it is critical in cases in which only one parent is involved in the abuse, and even arrested and incarcerated, that the school psychologist do what is possible to support the nonoffending parent. Studies repeatedly demonstrate that the mental health of nonoffending caretaking parents is closely related to the recovery of their children who have been victimized (Tharinger & Horton, 1992). While school psychologists may hold to common myths that nonoffending caretaking parents in every case have somehow colluded in abuse of the child, this is not accurate. Research demonstrates that nonoffending parents are a heterogeneous group. While some may have had some knowledge or involvement in instances of abuse, other nonoffending parents were not involved or even aware of the abuse and took immediate protective action when they became aware of it (Tharinger, 1991). For the child's sake, nonoffending parents need support.

While school psychologists are clearly not in a role to be the primary therapist for parents, there may be situations in which crisis intervention with parents is appropriate (Tharinger, 1991). For example, in situations in which the reported child abuse is so severe that the perpetrator is arrested at work, and the child is taken to the police station to make a formal statement, someone must be there for the nonoffending parent. The school psychologist may be in a role to assist in explaining to the mother why her child has not yet arrived home from school, what is happening, and where she might get help. Further, there may be ongoing opportunities for education/consultation regarding the child's emotional, behavioral, or academic response to the trauma (Tharinger, 1991).

Making referrals. As noted above, school psychologists will not be the primary therapists for parents. In most cases, they should not serve as the primary therapist for children either. Most school psychologists do not possess the expertise or experience to deal effectively with the problem of abuse. Therefore, the most realistic intervention provided by a school psychologist may be an intelligent referral (Brassard et al., 1983). Helping parents locate available resources may be the most valuable service the school psychologist provides (Brassard et al., 1983).

Quality referral work does not simply mean giving the parents a long list of providers. Instead, school psychologists must build a network of community services (Gelardo & Sanford, 1987). They must keep current on which providers have the specific expertise needed, how long waiting lists are, and which agencies have sliding fee scales. Additionally, once the referral is made, the school psychologist will want to be aware of and cooperate with treatment plans developed by other mental health professionals.

Specific/Optional Roles

Direct interventions. Once again, the school psychologist who does not have the time, the interest, the therapeutic background and training, the personal therapeutic experience, and other professionals to consult with in time of crisis, should not attempt to treat a maltreated child (Brassard & Appilaniz, 1991). However, school psychologists who have such interests and resources may choose to specialize in this area.

Best practices regarding therapy with children who have been victims of maltreatment will address affective, cognitive, and behavioral concerns in the context of a safe, supportive relationship. Regardless of one's theoretical orientation, an important aspect of treatment is the attempt to demonstrate the potential for safe, rewarding human interaction in the relationship with the maltreated child (Gil, 1991). Until a child feels safe and connected to the therapist, there will not likely be much response to treatment (Friedrich, 1990). While such cautions are generally assumed in therapy with any child, for the maltreated child, who feels extremely vulnerable, they are of utmost importance (Gil, 1991). Not only is the relationship critical for the work to be done immediately, it contributes immeasurably in creating a positive and meaningful experience in case the need arises for future therapy (Friedrich, 1990).

In the context of a safe relationship, a child can begin to explore and ventilate affect, including anxiety, frustration, rage, anger toward the offender, and grief for all that has been lost (Brassard & Gelardo, 1987; Wheeler & Berliner, 1988). Play therapy techniques may be appropriate for the expression of such emotions (Gil, 1991). Initially, children may need to learn to recognize their own feelings of emotional pain, as well as the feelings of others (Lewis, 1992). Additionally, children may need assistance in specific coping techniques to handle overwhelming emotions outside of therapy. For example, relaxation techniques may be used to assist children in reducing anxiety. Bedtime rituals may be helpful with night terrors and insomnia (Wheeler & Berliner, 1988).

In addition to expressing the related emotions, children who have been maltreated must learn to make sense of what has happened to them. Distorted, harmful cognitions often result from abusive experiences. While each child's experience is unique, the following conclusions are common among children who are being abused:

1. I am being hurt, emotionally or physically by a parent or other trusted adult.

2. On the basis of how I think about the world thus far, this injury can only be due to one of two things: Either I am bad or my parent is bad (the abuse dichotomy).

3. I have been taught by other adults, wither at home or in school, that parents are always right, and always do things for your own good (any other alternative is very frightening). When they occasionally hurt you, it is for your own good, because you have been gad. This is called punishment.

4. Therefore, it must be my fault that I am being hurt, just as my parent says. This must be punishment. I must deserve this.

> 5. Therefore, I am as bad as whatever is done to me (the punishment must fit the crime; anything else suggests parental badness, which I have rejected). I am bad because I have been hurt. I have been hurt because I am bad.
>
> 6. I am hurt quite often, and/or quite deeply; therefore I must be very gad. (Briere, 1991, p. 28)

Clearly, such distortions are understandable, given the abuse experience, yet very destructive. Children must learn to process and make sense of the trauma in a way that can be tolerated (Gil, 1991).

Maltreated children must learn to understand the abuse experience differently and to view themselves differently (Friedrich, 1990). Specifically, it is important that children who have been abused alter their attribution of responsibility for the abuse so that they can explain the offender's behavior in a way that allows them to "get off the hook" and have a restored sense of self-efficacy (Wheeler & Berliner, 1988). Thus, various cognitive approaches, adapted to the child's level, may be appropriate for gently challenging previous interpretations and providing more useful cognitions. Additionally, cognitive interventions are also important as a precedent for behavioral interventions (Garbarino, 1987). As long as a child thinks "I must be bad," he has little motivation to learn to "act good." A restructured cognitive map may allow the child to incorporate new behaviors.

Behavioral interventions are appropriate in efforts to deal with maltreated children, largely to build up the elements of social competence (Garbarino, 1987). Enhancing a child's prosocial reportoire may be especially important, given the inappropriate models many children who have been abused have experienced (Kolko, 1992).

Specific behavior goals and techniques will vary depending on the child's current functioning (Friedrich, 1990). For some, social skills training may be imperative because of problems with impulsive, withdrawn, and/or aggressive behavior (Haskett & Kistner, 1991; Lewis, 1992). For others, sexualized behaviors must be addressed (Wheeler & Berliner, 1988). For most child victims, assertiveness training that includes a repertoire of specific coping techniques may be helpful in decreasing the likelihood of future abuse. While the burden of child abuse prevention should never rest on the shoulders of children (Tharinger et al., 1990), children may be able to learn to avoid specific high-risk situations and may learn how to disclose abuse more readily.

While a relationship-based intervention plan designed to address affective, cognitive, and behavioral aspects of a child's life may be very effective on an individual basis, group experiences, which are more time-efficient and allow victims to see they are not alone, may also address multiple effects. A good example of such a program is a structure-time-limited therapy group for sexually abused preadolescent children (Corder, Haizlip, & DeBoer, 1990). This program incorporates a balance of affective, cognitive, and behavioral interventions. Cathartic exploration of feelings is prompted through art and story-telling exercises. Cognitive relabeling and self-esteem building are addressed through role-play and chants and cheers. Structured group exercises are designed to develop specific coping skills. Resources that include additional specific therapeutic techniques are listed at the conclusion of this chapter.

Prevention. An additional role for school psychologists with the interest and resources for involvement is in the area of child abuse prevention. School psychologists may have the opportunity to develop and/or implement prevention programs for school districts.

If so, the school psychologist must be aware of strengths, limitations, and possible unintended consequences of existing prevention programs (Consentino, 1989). There are many issues to consider when selecting a prevention program, including the developmental sensitivity, empirical ground, and the complex mixed messages that some programs may unintentionally send (Tharinger et al., 1988).

School psychologists, hopefully on committees with other professionals, must carefully consider these issues. Further specific goals should be considered before a program is implemented and the needed support should be in place before beginning the program. For example, if schools are going to do a series of assemblies regarding child maltreatment, they should be sure that a reporting plan is clear and that the school mental health professionals are prepared to respond to disclosures (Tharinger et al., 1988).

Furthermore, committees should carefully consider decisions regarding format, length, and the incorporation of the program into a broader health curriculum. It is important that programs directed at children include special education children as well, since they may be more vulnerable to abuse (Tharinger et al., 1990).

Additionally, parents should be included in the prevention process. School psychologists should collaborate with parents regarding prevention programs for child audiences and should consider directing prevention efforts to parent audiences (Consentino, 1989). For example, schools may consider offering parent support groups to prevent physical abuse of children (Gerler, 1991).

In addition to providing specific prevention programs for children or parents, some school psychologists may be involved in larger national and cultural fronts. "We need to be activists in fighting for the psychological rights of current and future students in our schools" (Erickson & Egeland, 1987, p. 166). School psychologists should be involved in advocating for change at this level, since major societal change is necessary for real and lasting improvement (Brassard & Gelardo, 1987). Such efforts might include lobbying for specific legal changes through NASP and other professional organizations or lobbying for prosocial media presentations that directly address these concerns (Brassard & Gelardo, 1987).

Finally, in considering prevention, school psychologists must look at the schools themselves (Brassard & Gelardo, 1987). One should consider the psychological climate of the school. Is it positive? Does it promote mental health and/or recovery? Teachers may be targets of prevention efforts so that they do not develop a pattern of psychological maltreatment (rejecting, isolating, terrorizing, ignoring, or corrupting) but rather create a climate that bolsters self-esteem in students and that presents a model of nurturance (Garbarino, 1987).

Self-Care Issues

School psychologists who choose to specialize in a field of child maltreatment must take measures to protect themselves. Child abuse brings up feelings of hostility, sadness, and helplessness as well as protective impulses (Gil, 1991). Stress arises from personal investment in difficult situations (Johnson, 1989). For some, old personal issues are brought to the surface (Friedrich, 1990). Work in this field is simultaneously rewarding and demanding (Gil, 1991).

Clearly, there is a need for continuing education regarding child abuse (Tharinger et al., 1989). It is important to recognize, however, that attending conferences only on this subject and reading professional literature solely in the area of child maltreatment may be overwhelming. While there is an urgent need for experts in this area, professionals will survive longer if they also attend to other arenas of professional development as well to balance their caseloads (Gil, 1991). A school psychologist should not work only with severely abused children, but rather should balance the load with more minor behavioral or emotional concerns. Additionally, supportive collegial relationships are imperative for all that work in this disturbing field (Friedrich, 1990).

SUMMARY

School psychologists are increasingly being identified as among the critical respondents to the tragic phenomenon of child maltreatment. Physically, sexually, and emotionally abused and neglected children fill our schools. School psychologists, therefore, must maintain an awareness of issues regarding child abuse and neglect, so that they are prepared for multiple levels of response. All school psychologists should be prepared for roles involving detecting and reporting child maltreatment, consulting with teachers and parents, and making referrals for needed services. Additionally, those who wish to specialize may provide direction intervention services and/or design and implement prevention programs. Because of the distressing nature of this work, school psychologists involved in the response to child maltreatment are urged to practice self-care by keeping balanced perspectives and case loads so that they can continue to respond effectively.

ANNOTATED BIBLIOGRAPHY

Briere, J. N. (1992). *Child abuse trauma: Theory and treatment of the lasting effects.* Newbury Park, CA: Sage.

This work provides a helpful review of relevant research and clinical literature and considers the interrelationships between all forms of child maltreatment, recognizing that they rarely occur in isolation. The treatment portions of the book, which are primarily focused on adult survivors, could be helpful to the school psychologist working with adolescents who have been victimized.

Friedrich, W. N. (1990). *Psychotherapy of sexually abused children and their families.* New York: Norton.

After reviewing literature regarding the impact of child sexual abuse and suggesting a model of coping, this work outlines treatment goals and gives specific suggestions for therapeutic work with sexually abused children. Throughout both assessment and intervention sections, family issues are carefully considered.

Garbarino, J., Stott, F. M., & the faculty of the Erickson Institute. (1989). *What children can tell us.* San Francisco: Jossey-Bass.

This book serves as a guide to help adults understand what children are trying to communicate, particularly in cases in which they may be attempting to disclose some type of abuse. Specific interview techniques are recommended, and other forms of communication (such as behavior, play, and psychological test responses) are addressed.

Gil, E. (1991). *The healing power of play: Working with abused children.* New York: Guilford.

Following a discussion of the impact of child maltreatment and the resulting therapeutic issues, Gil offers practical suggestions for play-based, child-oriented therapy with abused children. Clinical vignettes of treatment with victims of various forms of child maltreatment are included.

Hindman, J. (1991). *When mourning breaks.* Ontario, OR: AlexAndria Associates.

Dispelling common myths with research, Hindman discusses factors that mediate the impact of child sexual abuse and proposes a model of trauma assessment. Also included is a compilation of over 100 specific treatment activities, indexed by age — many that could be appropriate for school-based individual or group sessions.

Best Practices in Assisting Families Who Move and Relocate

Frederic J. Medway
University of South Carolina

OVERVIEW

This chapter is intended to provide a framework and guidelines for deciding the best professional practices for school psychologists to follow in order to answer questions, make decisions, and take actions relevant to clinical situations in which family mobility is of concern. The chapter will attempt to clarify the impact of relocation on children and their parents and provide guidelines and resources for intervention. To develop this framework it is necessary to first operationalize, as best possible, the concept of mobility and describe various variables associated with it. Next, research studies on the effects of moving are described. Finally, ways that school psychologists can contribute to situations in which mobility is a factor are considered.

BACKGROUND

Each year more than 17% of all American families change residence. This figure includes nearly 9 million children of school age (U.S. Bureau of the Census, 1990). More strikingly, each year approximately 30% of families with preschool children change residence and some types of families, such as those associated with the military, often relocate every 2 years.

Although most families who move remain within the same city, county, or standard metropolitan statistical area (van Vliet, 1986), residential mobility often accompanies social mobility. Residential moves are made by upwardly mobile families who seek larger or more luxurious housing and lower income groups who move because of financial hardship. These short distance moves often result from family separations as well. Thus, even short distance moves can involve many family changes. These include parent occupational, social, and lifestyle changes, changes in children's familiar surroundings, and often, school changes.

About one in six moves is to a different state or country. Occupations in the corporate world, sales, academia, the clergy, government service, and the military often require such moves. Interstate and international moves also characterize migrant and immigrant families. Just during their school years children may relocate many times. One survey of nearly 7,000 high school students found that 5.5% moved seven or more times (Norford, 1991).

Even one act of relocation places many demands and challenges on individuals. It is difficult to leave friends, family, and familiar environments and develop new relationships. Feelings of anxiety, loneliness, a sense of loss, and uncertainty are common. For children these worries typically center around losing friends and making new ones rather than changing school or adjusting to a new place (Norford, 1991). At least theoretically it is assumed that a stable reference group of friends and associates is important in order to get feedback on one's abilities and thus to develop a stable self-concept. Although early studies of relocation tried to link it with social and psychiatric problems, the research literature generally shows that children who are well adjusted prior to relocating are well adjusted after relocating whereas children with academic or adjustment deficits preceding a move tend to be at risk for similar or greater problems after a move.

In short, as will be demonstrated subsequently, there is little evidence to support the widely held belief that moving has negative effects on average children. This belief basically is based on case study reports, clinical impressions, and methodologically flawed studies (e.g., small and selected samples, lack of experimental controls). It also tends to be validated by the personal experience of some individuals. It further is compounded by media accounts of moving as "traumatic" for children. Although these erroneous beliefs regarding children and moving have been challenged (Goldsmith & Clark, 1987), even school professionals continue to be unduly concerned about the negative side of moving.

BASIC CONSIDERATIONS

The Process of Moving and Relocation

There is general consensus that family relocation should be viewed as life-transition and adjustment processes. With this view relocation can potentially have either positive or negative effects on families and, in most instances, involves some combination of the two. These effects can be short-term and result in changes transient in nature or long-term and alter previously established behavior patterns for many years. The impact may be a direct effect of environmental change on the child. The impact of moving may be mediated by changes in the family system or more likely, the results of moving may reflect some combination of the two.

There also is general support for the notion that moving involves a series of interrelated stages. At each stage there may be adjustment difficulties and accordingly opportunities for school psychologists to provide assistance. These intervention opportunities are described in the closing section of this chapter. The stages of family relocation can be broken down as follows:

- *Stage One: Anticipation and Preparation.* This stage generally is marked by families' facing a moving situation and considering the advantages and disadvantages of relocating. It involves all aspects of decision-making regarding relocation (possibly including solicitation of the child's input), parents' attitudes, and ultimately communication of the decision to the child. Research is clear in indicating that the vast majority of children are unhappy, sad, or scared when they hear they have to move (Khleif, 1978). They conjure up all kinds of hypothetical negative events and minimize positive benefits. This likely is especially true of younger children who lack formal operations thinking. Adequate explanation of the reasons for the move, upbeat and optimistic parent attitudes, and child reassurance are essential first steps for making the transition successfully. In fact, parents' attitudes and the opportunity for forming new friendships are the two most important variables in ensuring a successful move.
- *Stage Two: Planning.* This stage involves all actions necessary to make the move smoothly. This may involve elements related to house sale, selection of neighborhoods and schools, inquiries about community resources, and transfers of school records. Without proper planning, parents may feel irritable, overwhelmed, and fatigued, and these feelings often affect child behavior.
- *Stage Three: Moving Day.* Moving day is characterized by the actual relocation of the family and its possessions. Because only one in four families uses a moving company, this day is highly stressful. Young children may be particularly upset during this time.
- *Stage Four: Initial Adjustment.* This stage, lasting upwards of 6 months, is characterized by those actions taken by the family, child, and community resources to deal with the stresses associated with environmental change. This may involve increased financial responsibilities, securing new employment for family members, and adjusting to changing work or travel schedules of the breadwinner(s). Families hope that the child's behavior in the new home, school, and neighborhood will be similar to (or in some cases better than) the prior location. There is little disagreement among clinicians and researchers that initial adjustment difficulties are normal and expected.
- *Stage Five: Later Adjustment.* This stage involves the long-term impact of a move or series of relocations.

Many families feel relatively well equipped to deal with Stages Two and Three. Often they are assisted by businesses and moving professionals with these issues. By contrast, Stages One, Four, and Five have been the concern of social scientists.

Mobility Dimensions

Beyond acknowledging that moving represents a series of activities and subsequent adjustments school psychologists need to recognize that the events themselves vary dramatically from one moving situation to another. Even situations which appear similar on the surface such as a military transfer are not experienced the same by all children. Rather, moving and relocation vary across many different dimensions, and each of these, either singly or in combination with others, will influence moving-related reactions.

These dimensions are presented in Figure 1. Each of these can impact on various aspects of children's social adjustment, including peer relations and friendship networks, participation in social activities, mental health, including anxiety, self-concept, age-appropriate behavior, loneliness and susceptibility to depression, and school performance.

Mobility characteristics. Several variables associated with the move itself have the potential to impact on children. Three of particular importance are the distance moved, the degree of perceived choice, and the reason for the move. Although distance as measured by miles from old to new residence has little consistent impact on children, it must be recognized that even short moves can potentially exaggerate existing problems if they involve significant life changes such as an extended commute or a school change. Moving usually is hardest on family members who have had little say in the decision to move, the place of new residence, and other factors such as the school and neighborhood. Typically, this is the child and relocated spouse involved in corporate and military-related moves. Transplanted spouses are likely to have initial feelings of loneliness, depression, and loss, and these feelings in turn may affect their atti-

FIGURE 1. Variables associated with family mobility.

Mobility Characteristics

---

tudes toward the move and parenting skills. Thus, children may develop problems because parents are less functional. In some cases, roles may be reversed, and the child may feel pressure to support the parent. Research also shows the important role of the reason for the move. Families may move because of financial hardship, the requirements of military duty, separation or divorce, occupational necessity, or simply to secure more adequate housing. Single-parent families move more often than two-parent families. Children who move as a result of divorce report less involvement in school social activities in the years following a move (Norford, 1991) compared to nonmovers, even when stressful life events are controlled.

Child characteristics. The stresses associated with moving affect children in different ways and this appears to be influenced by developmental levels, gender, and psychological risk factors. Several studies have directly examined children of different ages following a move and found no clear developmental patterns. Nevertheless, the bulk of the literature suggests that the most vulnerable ages to moving-related stressors are the preschool years and during early adolescence (Vernberg, 1990). This is contrary to the general public view that the best time to move is before children start elementary school and that moving is hardest on high school students. Preschoolers have difficulty dealing with the changes in familiar surroundings, lack the coping skills of older children, and have trouble cognitively understanding the need for the move. Also, they are less likely than older children to understand abstract concepts of time such as "in six months" which may relate to when the move will occur. Young adolescents report about three times as much difficulty forming friendships as do children in the primary grades (Barrett & Noble, 1973).

Gender does not appear to have consistent effects on mobility reactions, although some have argued that males react more negatively than females to relocation (van Vliet, 1986; Vernberg, 1990) and to a variety of associated transitions (Rutter, 1981). Males appear to have a harder time leaving old friends and making new ones (Donahue & Gullotta, 1983). On the other hand, Brown and Orthner (1990) found that recent moves and frequency of mobility history were more strongly associated with low life-satisfaction among female than male adolescents. Second, males are more likely to rely on and experience rejection from peers than females. And, third, males are more negatively reactive to a variety of life transitions (Rutter, 1981).

Finally, it has been recognized that children with existing academic and behavioral problems require structure, consistency, and special attention. Typically, therefore, moving or any potential stressors is likely to impact such children to a greater extent than children without pre-existing problems. Kantor (1965), in one of the few studies to assess children both before and after moving, showed that negative mobility effects were attributable to initial behavioral differences between children, not mobility per se.

Family characteristics. It is virtually impossible to disentangle the effects of family variables from the impact of relocation. It is the family who informs the child of the move; deals with concerns and anxieties; makes the relocation decisions; and attempts to help the child through the transition period. If the family attitude toward moving or toward this particular move is negative it is likely that the child's will be as well. Several studies have underscored the importance of the mother's attitude toward the move on children. Norford (1991) reported that over 60% of mothers who had relocated their children an average of seven times reported moving as either "moderately" or "very" stressful. Further, if either parent becomes overanxious, withdrawn, physically stressed, or intolerant this too will affect the child, particularly if the child connects this behavioral change to the move. In corporate families the needs of the head of the household may so overshadow the needs of other family members that problems develop. Several studies indicate that moving can result in depression but only when family support and social cohesion is low. By contrast, selective attrition of service personnel in the military system may have resulted in large numbers of families basically accepting of the mobile lifestyle and therefore communicating these positive relocation expectations to their children.

School factors. School factors are an important, although unstudied, moderator of moving-related reactions. School size, quality of teacher–student interactions, opportunities for leadership roles, curriculum demands, policies and norms, and the nature of support services all would appear to impact on mobility adjustment. Occasionally school experiences can certainly exacerbate moving reactions. For example, considering the effects of group cohesion, it is not surprising that elementary-age males who enter school late in the year are less likely to be accepted socially than boys who enter early in the year. Schools characterized by existing cliques create challenges for the newly relocated adolescent. However, in most cases, schools have had little systematic impact on mobility issues due to their general failure to address this population. One review found only two large-scale school intervention programs to ease the transition discussed in the literature (Blair, Marchant, & Medway, 1984). One program, known as the Summer Visitation Program (Keats, Crabbs, & Crabbs, 1981), used school counselors to (a) make new school families aware of school policies using home visitations; (b) involve these families in school and community activities by sponsoring various outings enabling the families to meet others in the community; and (c) develop support groups for recently relocated children. This program was successful in increasing social contacts and happiness and reducing absenteeism in participating students compared to nonparticipating controls. A second program, known as Students Assimilated into Learning (Panagos, Holmes, Thurman, Yard, & Spaner, 1981), also sought to increase parental involvement in the school and, in addition, made use of staff development activities and special learning centers to quickly assess the educational status of students moving into the school and provide assistance with academic deficiencies. Data obtained from this program indicated that served students showed increased achievement scores.

In one area, however, schools have played a questionable role regarding the mobile student. Many schools have policies or philosophies encouraging grade retention of new students and, in fact, research shows that highly mobile children are retained more often than nonmobile children. *Light's Retention Scale* is a questionable assessment tool which inappropriately includes mobility as a factor to consider in deciding whether to retain a child. A survey (Norford, 1991) of adolescents who had moved at least six times indicated that only 15% indicated feeling behind academically after moving. Given that retention itself is a questionable practice and that research indicates mobility generally is not a major stressor for most children, there is nothing to recommend retention of mobile students and much support for rejecting the practice.

Community factors. The similarity of new communities to old ones helps moderate the stress of relocation. Moves which subject children to cultural and subcultural differences are presumed to require greater adjustment. Along these lines it is often assumed that moving from one military base to another is generally not highly stressful because (a) bases tend to be similar and (b) the base tends to insulate the military family from the surrounding community. In addition, relocation support services are available through military-supported Family Service Centers. While this may be true, there is no empirical evidence that children in military-related moves do any better (or worse) than children in corporate moves.

The Impact of Relocation on Children

In attempting to understand the impact of relocation on families it is not only important to consider the stages of moving and the various elements associated with the process but also to realize that there are vast differences in the public view of mobility as compared to the scientific community. The following three excerpts are typical of how mobility is perceived by many citizens and by the media.

> *Sesame Street Magazine:* Samantha and Robert Brown had been preparing for moving day for weeks. On the big day, Samantha left her one-year-old son with a neighbor while she and her husband supervised the movers. Eight hours later it was time for one last look around. With the baby in her arms, Samantha entered his now-bare room. He took one startled look and began to bawl. Brown was surprised at the force of her infant's reaction: "There was no question. He knew something was terribly wrong." Like most infants, Brown's baby suffered only momentarily, because the real center of his world was his parents . . . But for most kids, be they toddlers or teens, moving can be stressful. (Rouhana, 1990, p. 19–20).
>
> *Boston Globe:* Whether you are relocating across town or across country, moving is traumatic for children of any age. The change in routine, parents' preoccupation with the move, giving up friends — these are all losses for the child. The worst mistake parents can make is to underestimate their importance. (Maltz, 1992, pp. 67, 71)
>
> *New York Times:* Daniel and Gerry Barnett hadn't expected their children to react so strongly to the family's move from Oklahoma to suburban Chicago. Twelve-year-old Helen told her parents that she looked forward to the move because it was "a neat thing to do." . . . But as the move approached, she became more obstinate when an adult asked her to do something. She would overreact to ordinary events. Helen's school grades dropped slightly in the next marking period. (Kutner, 1988, p. 21)

In short, both the popular press and general opinion view moving as a potentially traumatic event that can have long-term consequences on children's mental health and school performance. This view tends to be shared by teachers and school administrators. By contrast, although research suggests that there may be some short-term impact of mobility on children, data obtained from more than 100 studies of children's relocation indicates that there is little evidence for any long-term negative impact. The following is a brief overview of research in this area drawn from earlier reviews by Norford (1991) and van Vliet (1986).

Academic achievement. Achievement of mobile versus nonmobile populations has been the most widely researched area. Across 18 of the most methodologically sound studies (out of over 40 conducted) there is virtually no effect of mobility on school achievement once initial achievement levels are controlled. Mobility does appear to hurt the academically underprepared student. Further, in six studies measuring grade retention, mobile students consistently are held back more often than nonmobile students, despite the fact that in three of these studies achievement levels of mobile and nonmobile students did not differ.

Social adjustment. Does frequent relocation undermine self-image, peer relations, participation in extracurricular activities, and other areas of social adjustment? Most research suggests that it does not. High-frequency and low-frequency movers have not been found to differ on traditional scales of self-concept and personality. There is some evidence that depression may be associated with higher levels of mobility in young adolescents. However, it is not clear if, in these studies, depression arose after the move or during earlier preparatory stages. In one recent, well-controlled study (Norford, 1991) there were no differences in depression and perceived social support among high school students varying in mobility history, including nearly 100 students who had moved seven times on average. Norford did find that frequent mobility after seventh grade did significantly affect participation in extracurricular activities. Norford measured potential positive adjustment indicators as well and found no consistent positive effects associated with high mobility.

BEST PRACTICES

With an awareness of the prior background information and appropriate training in assessment, child development, and intervention, school psychologists should have the basic skills to deal with relocation concerns. School psychologists are likely to encounter mobility issues in two primary contexts. First, in their capacities as school consultants, psychologists occasionally are asked to provide information about relocation to various sources. Those seeking this information most likely are parents (those considering relocation or those who have just relocated), teachers (faced with making decisions about newly transferred students), school administrators, and, occasionally, the media. Parents may be prone to worry about mobility effects far more than is warranted. Norford (1991) found that 27% of approximately 95 adolescents who had moved six times or more viewed moving as "very positive" for them compared to 15% of their mothers. Only 3% of the students viewed moving as "very negative" compared to 10% of their mothers.

Typically, however, families new to a community do not pose these questions to school psychologists. If their child has not had school problems in the past or if the parents are unfamiliar with school resources, it is unlikely that psychologists will be called. Best practice, therefore, dictates that school psychologists inform those in the community such as doctors, the clergy, and key people in school district administration of their knowledge in this area.

Second, in their roles as providing intervention services, school psychologists may be called upon directly to (a) develop programs to ease mobility transitions or (b) work with children having difficulty with mobility-related adjustments. The following section reviews several best practices and helpful sources to aid in both capacities.

Parent Consultation

Parents who contact school psychologists for information about moving may do so at any stage of the relocation process. Typically, these parents fear that moving will upset their child in some way and desire practical tips and resources to make the move easier. Figure 2 presents a list of practical information that families and the media can be provided. This list addresses many questions parents have about moving. Further tips are presented in books specifically designed for parents listed at the end of this chapter. These can be useful provided the reader keeps in mind that most popular books overdramatize the negative effects of mobility. In addition, school psychologists can encourage parents to use one or more of the children's story books listed in Figure 4 to clarify relocation feelings and let the children know that their feelings are not unique. Also, most of the major moving companies have materials to aid families with moving. A brochure entitled *Moving with Children* can be obtained from United Van Lines, One United Drive, Fenton, Missouri 63026. Ryder Truck Rental has a "Movers Advantage" package that includes games and activities for children. It can be obtained by calling 305-593-3183.

School Professional Consultation

School psychologists are encouraged to share the information in this article with school teachers, counselors, and administrators. Specific guidelines for teachers are presented in Figure 3. In addition, psychologists can be given the names of all recent movers and check with teachers on their progress after a period of time. Particular attention should be given to newly transferred males given research showing their greater vulnerability to moving-related stress and their decreased reliance on appropriate coping mechanisms compared to females.

Program Development

School psychologists can take the lead in developing school-based preventive programs centered around relocation issues. In particular, aspects of the Summer Visitation Program (Keats, Crabbs, & Crabbs, 1981) reviewed earlier, can be developed by special service teams, particularly in areas characterized by high transiency. Given the empirical validation of this program, it represents one of the few validated best practices in this area. In addition to interventions with students just entering school, counseling groups can be organized for elementary school children whose families will soon be moving to other communities. In such groups children can be given an opportunity to share feelings about moving and discuss specific strategies such as social skills training to use in saying good-bye and making new friends. Programs also can be developed for parents to help them understand the impact of moving as it relates to their own specific circumstances and the development of their child. It is very important to tailor intervention programs, teacher inservices, and parent education groups to the age of child clients.

Counseling and Therapy

As indicated previously, it is unlikely that school psychologists will encounter large numbers of students with serious problems such as depression, withdrawal, physical symptoms, or dramatic achievement declines that necessitate extended counseling. Adjustment problems are normal during the first 6 months after relocation and typically can be handled through family or teacher consultation. Unusual withdrawal, anxiety, anger, stress-related reactions, acting-out, or academic problems, however, do require early intervention. Several nonbehavioral techniques (cf. Medway, 1985) are particularly appropriate. These include play therapy, role playing to bring conflicts into awareness, and bibliotherapy. The children's literature on moving listed in Figure 4 is suited for treatment designed to help children gain insight into their problems and to develop alternative courses of action. The video *Let's Get a Move On!* is especially engaging and has won several educational awards. Additionally, social skills training can be used to aid in building friendship networks and dealing with negative remarks made by others. Because many contextual factors such as family dynamics and household economics may affect the child more than just environmental change and adjustment, consultation and therapy in cases involving relocation require extensive problem-identification activities prior to treatment.

FGURE 2. Parent tips on relocation.

1. Discuss the move openly and honestly with children once the decision to move is definite. Older children should be given at least 3 months notice, if possible, to prepare for the move. They should also be given some input into family decisions. For younger children, it is preferable to wait until moving is closer, such as when moving-related activities change family routines. For younger children, reading story books about moving may stimulate questions, elicit feelings, and easy any anxiety. Toys, such as trucks and wagons, can be used in "moving games" to illustrate the concept of moving to the 2- and 3-year-old child. Be clear the move is final and avoid promises you may not be able to keep.
2. Try not to move during other upheavals in the child's life such as right after a sibling birth or following a divorce or parent death. This will compound the stress and adjustment demands placed on children.
3. Get children involved in the move. Encourage children to take on projects designed to gather information on the new community. Subscribe to the newspaper in the new community.
4. Start building a new community network before the move. Inquire about religious groups, medical and social service facilities, educational opportunities, newcomer's assistance, and children's activities such as scouting. If relocation is due to corporate or military transfer, inquire about special assistance offered.
5. Recocognize your own stress level and don't take on more than you can handle. Moving yourself, looking for a house without an experienced real estate agent, or moving into a home requiring repairs and renovation can serve as added stressors. Recognize that your stress level as well as your attitude about moving will affect your child's behavior.
6. Make sure that all medical and school records are sent ahead. These should include a birth certificate, achievement tests, immunization records, and relevant school correspondence. Special education transfers should provide psychoeducational assessment results, health screenings, and Individual Education Plans.
7. Take responsibility for orienting your child to the new school and community. Have a meeting with your child's teacher to discuss the placement. Inquire about any special programs or assistance provided by psychologists and counselors for relocated students. Do not allow your child to repeat a grade just on the basis of a move. If retention is recommended, insist on a full, individually administered evaluation and, if necessary, a second opinion.
8. Although a move during the summer is less likely to be disruptive to children's school performance, a move during the school year brings children into immediate contact with others their age. Also, teachers and classmates are more likely to treat them as special when they enter during the year than at the start of a new year.
9. On moving day reassure children that their possessions are going to the new home. Allow children to pack a small suitcase to carry with them with special playthings, momentos, and pictures. Load the furniture of young children last so that these items are first to be unloaded and placed in the new home. Once in the new home, allow the child some say in how the room will be decorated or try to arrange it similarly to the last arrangement. Make the first night in the new home special by having some kind of party.
10. Goodbyes should be allowed to occur such as going-away parties. Encourage children to make scrap books with pictures of old friends and to keep up correspondence.
11. Take the initiative, especially during the initial weeks of a move, to actively explore the new environment. Make an effort to meet people. Invite neighbors over and volunteer at the school. Avoid staying indors and devoting all your time to unpacking and arranging the new house. This should be a time spent with children.
12. Try to find positive things in moves required by financial hardships.
13. Moving may diminish teenagers' feelings of independence and need for control. Therefore, aid teenagers in exploring social opportunities in the new environment. Resist the temptation to be overprotective due to unfamiliarity with the new community.

FIGURE 3. School staff tips on children and relocation.

1. Present children who are moving with photo albums of classmates and friends. Consider having a going-away party for moving students.
2. Announce the arrival of new students. Make sure they are included in yearbooks and the like.
3. Assign student "buddies" to new students. Buddies may also serve as guides and peer tutors.
4. Encourage recently moved students to do presentations on the places they have lived.
5. Be sensitive to family stresses that may be associated with mobility. Note in particular financial hardships and provide the family with information about support services if needed.
6. Do not retain new school enrollees. Retention decisions, if made at all, should not be based on family mobility history or the ability of the child to adjust to new school routines. If academic or behavior problems are present, consult the school psychologist.
7. Maintain particularly close contact with newly relocated families so as to enhance school–home communication.
8. Participate in and encourage school-sponsored meetings and social events for parents of newcomers to acquaint them with school policies and community services.

SUMMARY

Each year one out of five families relocate in the United States. The process of relocation involves several adjustment stages and each, in turn, is influenced by a host of contextual variables such as reasons for the move, child age and gender, and aspects of the new community. Because moving does involve changes and interruptions in children's schooling and friendships there is concern among the public and school professionals about the effects of moving on children and their families. Despite this concern, research indicates that family relocations are far less stressful on children than many people believe. Although mobility can cause children to be anxious, to develop behavior problems, and to have academic problems in the classroom these problems typically are short-lived. Most normal children ultimately handle moving transitions well. Those who do not typically have presenting problems which originate before rather than after a move. Within six months to a year it is virtually impossible to distinguish movers and nonmovers on traditional measures of personality and achievement.

The keys to successful moves lie in family behavior and attitudes and in the opportunities available for children to make new friends and experience a consistent, known environment. Schools can positively impact in both these areas. Unfortunately, with the exception of some isolated efforts, schools often have ignored their important role as a key community resource in aiding mobile families during the transition to a new neighborhood (Blair, Marchant, & Medway, 1984). Thus, school psychologists can serve an important function in both advocating for school-wide efforts and including personal efforts to aid relocating families among their activities. Several best practices have been described. Family mobility is an integral part of the American lifestyle. By providing planned consultation and intervention services centering around relocation issues, school psychologists can bring to bear a variety of assessment, consultation, and intervention skills to a potential family dilemma.

Best Practices in Planning Interventions for Students with Attention Disorders

Margaret M. Dawson
The Center for Learning and Attention Disorders

OVERVIEW

With increased awareness on the part of parents, educators, clinicians, and researchers, concerning the nature of attention disorders and the effect they have on school performance and adjustment, school psychologists are becoming more involved in both identifying attention disorders and in developing effective interventions. Another chapter in this volume addresses diagnostic and assessment issues in the identification of students with Attention Deficit Hyperactivity Disorder (ADHD)[1]. This chapter delineates the range of interventions commonly used with students who have attention disorders.

This chapter addresses intervention needs of students diagnosed as having ADHD as well as those students who may not meet any formal definition of ADHD but who demonstrate problems in the classroom due to characteristics commonly associated with ADHD. By addressing a broad range of attention problems without undue emphasis on formal classification of students as ADHD, this chapter is congruent with NASP's Position Statement on Students with Attention Deficits (NASP, 1992). This statement acknowledges that reliable diagnosis of ADHD is difficult and recognizes "that it is difficult to distinguish attention deficits so severe as to require special education from the normal range of temperament and fluctuations in attention to which all students are susceptible." Furthermore, it is consistent with a consultation/problem-solving orientation toward the practice of school psychology. Problems with attention can be defined as deficits in a set of school-related behaviors. The task of the school psychologist is to work with teachers and parents to define those deficits, to develop interventions to address the deficits, and to help implement and evaluate those interventions. This chapter will describe briefly the behavior characteristics associated with attention disorders, delineate a problem-solving process to develop effective interventions, and then focus on the array of interventions that can be used to address the behavior and academic performance problems commonly associated with attention disorders.

BASIC CONSIDERATIONS

Characteristics of Students with Attention Disorders

The DSM-III-R (1987) provides the most commonly accepted definition of Attention Deficit Hyperactivity Disorder. This definition lists 14 characteristics, and requires that a student demonstrate at least eight of those characteristics for a duration of at least six months in order to meet the formal criteria for ADHD. The 14 characteristics primarily describe problems with inattention, impulsivity, and motoric hyperactivity.

Since DSM-III-R was published, many researchers and clinicians have argued that this definition of ADHD omits a significant population of students who exhibit attentional problems but may not be impulsive or motorically hyperactive. Frick and Lahey (1991), for instance, maintained that attention disorders and motor hyperactivity are two distinct behavioral dimensions, and that a significant number of students with attention problems do not have concomitant problems with hyperactivity or impulsivity.

Students with attention disorders *without* hyperactivity display the following characteristics: They often fail to finish tasks, they are easily distracted, they have difficulty listening, concentrating, and organizing their work, they require supervision to accomplish tasks, and they frequently shift activities. Students with attention disorders *with* hyperactivity display these same characteristics. However, they are also described as having difficulty remaining seated, exhibiting motor restlessness and excessive fidgeting, frequently calling out in class or interrupting, being always on the go, and often acting without thinking (Lahey, Pelham et al., 1988).

Another set of characteristics are associated with what Barkley (1990) called a "focused attention disorder," and these may make up a third distinct category of attention disorder. These characteristics include: "(1) often daydreams or is 'lost in a fog'; (2) is frequently 'spacey' or internally preoccupied; (3) is often confused or lost in thought; (4) often appears sluggish or slow moving; (5) often stares; and (6) often appears to be apathetic or unmotivated" (Barkley, 1990, p. 185). These youngsters are more often *underactive* than hyperactive, but can have attention problems that may profoundly affect school performance.

Although children with ADHD are commonly considered to have problems *paying attention*, for the purposes of developing effective interventions, it may be more useful to think of the disorder, as Barkley (1990) has postulated, as a biologically-based "motivational deficit." Youngsters with attention disorders appear to be insensitive to normal behavioral consequences, either positive or negative. Thus, the typical responses to behavior in school, such as praise, reprimands, or test grades, tend to be ineffective in shaping behaviors of children with attention disorders.

Viewing attention disorders in this light helps resolve some of the seeming inconsistencies these children display. Parents and teachers often comment, "But he has no trouble paying attention to things he enjoys!" (e.g., video games, favorite television shows). They also note that the quality of work these children produce in school can sometimes be exceptional, leading them to wonder why such children cannot produce work of high quality "all the time." A motivational deficit hypothesis would suggest that many of the problems these students encounter in school (and at home) occur because they have an inordinate amount of difficulty *making themselves do* tasks that are not intrinsically interesting to them.

This hypothesis would also account for another common characteristic of students with attention disorders: There is frequently an attention/task difficulty interaction, such that the students are most susceptible to attention problems on tasks that they find difficult. While people in general attend better to tasks that interest them, those with attention deficits show significantly greater problems attending to tasks that are tedious, difficult, or uninteresting to them. It takes students with attentional deficits an inordinate amount of effort (and hence requires greater motivation) for them to apply themselves to tasks and responsibilities that the ordinary student can accomplish with less effort and self-determination. An awareness of this characteristic can help the school psychologist develop more effective interventions to address motivational issues.

Additional characteristics of children with attention disorders, although they are not considered part of the disorder itself, co-occur frequently and thus may need to be the target of appropriate interventions. About 65% of children with attention disorders also display significant oppositional behaviors (Barkley, 1990). These children often resist authority figures and may become hostile and defiant in the face of requests for compliance.

Additionally, youngsters with attention deficits often have significant problems with peer relationships. Arising from impulsivity, problems reading social cues, and difficulty taking the perspective of others, these may make them appear self-centered and insensitive. And, as years of negative feedback from parents, teachers, and peers accumulate, children with attention disorders are at high risk for self-esteem problems as well.

Another common characteristic of students with attention disorders is academic underachievement. Although this sometimes is due to a concomitant learning disability that may cause skill deficits, more often these students have acquired basic academic skills but demonstrate difficulties with day-to-day classroom performance that stem from characteristics inherent in the attention disorder. Academic skills are delayed most often in written production, perhaps due to deficits in fine motor coordination, poor planning and organization, difficulty generating ideas, and problems sequencing thoughts. Some students with ADHD may also exhibit problems with reading comprehension — again, not because of skill deficits in either decoding or comprehension but because they have trouble concentrating on what they are reading sufficiently to grasp the meaning.

Finally, a significant number of youngsters with attention deficits exhibit problems with a constellation of behaviors referred to as "executive functions." Beside problems with sustained attention, executive function deficits may include problems with planning and organization, task initiation and follow-through, goal selection, anticipation of consequences of actions, and inhibition of impulsive responding.

It is important to recognize that all children with attention disorders (indeed, *all* children) bring a unique set of characteristics, both strengths and weaknesses, to any learning situation. While it is helpful to be aware of problems commonly associated with attention disorders, ultimately one must consider the specific needs of each child in order to develop interventions effectively tailored to those individual needs.

Designing Interventions

Effective interventions to meet the needs of students with attention disorders generally fall into three broad categories: modifying the attitudes and beliefs of those who work with students with ADHD; modifying the environments in which these youngsters live and learn; and modifying the behavior of the students themselves.

While it is generally assumed that the most effective way to help students with learning problems is to define clearly the skill deficits and then develop strategies to address those deficits, many experts in attention disorders believe that the place to start is with educating those who work with these students concerning the nature of the disorder itself. Barkley (1990) stated that "the actual initial target of intervention is the teacher's knowledge of and attitude toward the disorder of ADHD. For we have found that where teachers have a poor grasp of the nature, course, outcome, and causes of this disorder and misperceptions about appropriate therapies, attempting to establish behavior management programs within that classroom will have little impact" (p. 501).

Educating teachers and parents about ADHD can occur naturally while one works with individual students referred because of the disorder. School psychologists may accomplish this more efficiently, however, by conducting workshops and in-service training courses on ADHD. Conducting courses with sessions extending over several weeks may be more effective than doing "one-shot" workshops, particularly if time is built into these sessions for small group discussion and problem solving. This approach enables teachers to "live with" the concept of ADHD, to have more time to integrate new learning, and to have the opportunity to try out new skills and discuss the results with others.

It may be helpful to address attitudes and beliefs directly in these workshops. For instance, one small group activity might be to ask teachers to answer the following questions:

1. If you were the parent of a child with an attention disorder, of all the beliefs, attitudes, or values your child's teacher might have about ADHD, which do you think would be the most important?

2. If you were to walk into that teacher's classroom, what would you see that would let you know that your child's teacher has that value?

The resulting discussion would allow teachers to consolidate some of their thinking about attention disorders and to formulate beliefs and values that can have a positive effect on how they respond to children with attention problems.

Environmental modifications involve changing aspects of the student's environment to address learning or behavior problems. Examples might include seating the student near the teacher for whole-group instruction or allowing the student to come directly in from recess without having to wait in line. Behavioral modification consists primarily of developing incentive systems to increase the likelihood that the student will engage in appropriate classroom behaviors. These interventions are most effectively developed using a problem-solving format. This approach can be used in a one-to-one consultation between school psychologist and teacher or applied in a small group setting. Many school psychologists serve on teacher assistance teams that function in this way. Such an approach generally follows the following steps: (a) define target behaviors specifically; (b) brainstorm possible solutions; (c) select an appropriate intervention; (d) implement the intervention; and (e) evaluate the results. The chapter on behavioral consultation elsewhere in this volume provides further information about this problem-solving model.

This approach can be used with students whose attention problems range from mild to severe, whose needs can be met in the regular classroom with minimal modifications, or who may require something more formal, such as a special education plan or a Section 504 plan. Where something more formal is desired, the outcome of such problem solving may be a written plan that delineates the problem behaviors, the appropriate interventions, or accommodations, and the person(s) responsible for implementing the interventions. Figure 1 provides an example of such a plan.

BEST PRACTICES

Incentive Systems

As noted above, youngsters with attention disorders frequently do not respond to the natural incentives, both positive and negative, that are effective with other students. Extensive research has clearly demonstrated that positive reinforcement is highly effective in addressing problem behaviors associated with attention disorders. Behaviors that have responded successfully to positive reinforcement include sustained attention, activity level, time on-task, response accuracy, disruptive behavior, and social skills (Fiore, Becker, & Nero, 1993).

In its simplest form, a positive reinforcement procedure involves administering a reinforcer upon demonstration of an appropriate target behavior. An example would be allowing a student to spend the last 15 minutes before lunch playing a computer game with a friend after completing all required morning seatwork.

Simple reinforcement procedures, however, often are ineffective with children with attention disorders. Experts in ADHD (e.g., Barkley, 1993) offer suggestions and guidelines for establishing incentive systems:

1. *Ensure that reinforcers are administered immediately and frequently.* Some research suggests that continuous reinforcement systems are significantly more effective than partial reinforcement systems for students with ADHD (Fiore, Becker, & Nero, 1993). Thus, systems need to be designed carefully to ensure that the reinforcer can be administered consistently.

2. *Build variety into the reinforcement system.* Youngsters with ADHD often crave novelty and satiate very quickly on specific reinforcers. This problem

FIGURE 1. Sample Section 504 plan.

Area of Concern	Intervention/Accommodation
1. Written expression	1. Provide assistance with prewriting activities (brainstorming/concept mapping)
	2. Allow use of computer or dictation for longer assignments
	3. Provide assistance with proofing, preparing final draft
2. Long assignments	1. Break down long assignments into shorter ones
	2. Help student develop time lines for longer assignments
	3. Reduce writing requirements by reducing length and allowing alternative methods of demonstrating learning
3. Following directions	1. Provide written as well as oral directions
	2. Repeat group directions individually
	3. Have student repeat directions to show understanding
	4. Break down longer directions into smaller steps
	5. Build in incentives for following directions and for asking fo help
4. Distractibility	1. Preferential seating during whole class work
	2. Nonverbal signal from teacher to attend
	3. Quiet place to work during seatwork
	4. Cue for transitions
	5. Incentives for timely work completion

can be addressed by developing a reinforcement menu so that the student can choose from a variety of attractive rewards.

3. *Assume that whatever system is designed will require adjustments.* The expectation that the system will likely require some "fine tuning" to make it work effectively should be communicated to those who implement the system, lest they decide too quickly that the system has failed and should be abandoned. Whenever such a system is designed, arrange a follow-up meeting within a week or two, to "troubleshoot" and refine the program.

4. *Involve the student in helping to design the incentive system.* To the extent possible depending on the age of the child, the student should be a full partner in this process, giving input on target behaviors, realistic goals, and appealing reinforcers. Students themselves often have good ideas about how the system can be administered, including how to keep records and how often and under what circumstances to give reinforcers. When the program needs to be revised, students often offer valuable insights into how it can be improved. When students are active participants in the process, not only are they more likely to "buy into" the system, but they also can learn valuable skills in task analysis, goal-setting, self-monitoring, and self-evaluation.

Various reinforcement systems have been effective with students with attention disorders. Some of the options to consider are presented below.

Token economies. The use of secondary, or token, reinforcers gives a teacher more flexibility in what rewards can be earned and when they will be given. By giving the student "tokens" (or more often, particularly with older children, "points") for demonstrating appropriate target behaviors, the teacher gives immediate feedback regarding performance without having to give the reward right away. Such a system allows the child to earn a variety of reinforcers of varying values, since specific points values can be attached to each reward. This approach can be used with an individual student or with groups of students, with different target behaviors and reinforcers assigned to each student if desired. Reinforcers should include a variety of activity as well as tangible reinforcers. By building in group rewards, the aid of the whole class can be enlisted in helping the youngster achieve his or her goals, since all will benefit from the child's earning rewards.

Response cost. With response cost, earned tokens are withdrawn when undesirable behaviors occur. This approach has been found particularly effective in increasing attention to task and work completion, and, as with many other interventions, it appears to be particularly effective when paired with medication (Fiore, Becker, & Nero, 1993). Studies using commercially available electronic desktop counters also have shown positive effects on attention and work completion, thus making it easier to administer a response cost system (e.g., Gordon, Thomason, Cooper, & Ivers, 1991).

Home-school report cards. This approach combines several important features that make it an effective intervention for youngsters with ADHD. In addition to incorporating the components of a token economy (e.g., defining target behaviors and assigning points that can be exchanged for an array of reinforcers), it also enables parents and teachers to collaborate, building communication between home and school. This enables home and school to work together on mutually agreed-upon behaviors, and may help reduce other problems associated with ADHD, such as keeping track of academic materials and assignments, forgetting homework assignments, and the like. Finally, it expands the variety of reinforcers available for students to earn, since parents often provide attractive rewards that are unavailable in school (e.g., the opportunity to play a game with dad, the chance to rent a video game, or go on a family outing to a favorite place).

The steps to develop a home-school report are as follows:

1. Identify between two and four target behaviors. These may include either appropriate behaviors that should be increased, such as work completion or participation in class discussions, or inappropriate behaviors that should be decreased, such as speaking out of turn or making derogatory comments to classmates. It may be helpful to have as at least one of the selected behaviors a skill that the child already possesses, in order to reinforce positive behavior and to increase the likelihood that reinforcers can be earned each day.

2. Develop a rating scale with which the teacher can judge the child's performance on the targeted behaviors. Higher numbers should be equated with more successful performance. In this way, the ratings the child is given can equal the number of points the child earns that day.

3. Develop a list of possible reinforcers, with point values attached to each. It is helpful to include reinforcers that can be earned daily, weekly, and on a longer-term basis. As students get older, they may be most interested in saving points over a longer period of time for more substantial rewards, while younger children will find smaller, daily rewards the most attractive.

4. At the end of each day, the teacher and student together review the student's behavior and complete the home-school report card form. Some teachers like to have students fill out their own forms independently and then compare the results with the teacher's assessment. This builds into the process an important self-evaluation component.

5. If remembering to bring home the report card is a problem, the teachers at first have to ensure that the card is actually placed in the child's backpack. Additional points could be assigned for handing the report card to parents, and this added incentive is usually sufficient to ensure that the report card is transported safely between school and home. Alternatively, a response cost approach could be added, by allowing the child to earn points only for the days when he or she remembers to bring the report card home.

Figures 2 and 3 contain a sample report card and reinforcement menu.

Time-Out Procedures

With those youngsters with ADHD who are also disruptive or aggressive, the use of rewards or a response cost system alone may be insufficient to shape appropriate classroom behavior. For these youngsters, time-out is a common procedure. Technically, time-out is "the withdrawal of positive reinforcement contingent upon inappropriate behavior" (Barkley, 1990). In most cases, this means the removal of the child to a "time-out" area of the classroom away from the center of activity for a brief period of time (usually 2 to 10 minutes). If the disruptive behavior escalates, an additional consequence may be a loss of points or tokens or removal from the class (e.g., to another classroom or the principal's office).

Time-out can be very effective, particularly with young children such as preschoolers. Some cautions are worth noting, however:

1. The amount of time the student is expected to remain in time-out should be kept relatively brief. A general rule of thumb is 1–2 minutes per year of age. The clock does not start, however, until the child is sitting *quietly* in the time-out area.

2. The effectiveness of the procedure should be carefully monitored. If a child is being sent to time-out many times in a day and this frequency does not decrease over time, then one should assess why it is not having the desired effect. Some children are sent to time-out for behaviors that are not easily within their conscious control. An example of this might be sending a preschooler to time-out for impulsive behaviors in response to provocation by another child. Sometimes, the work children are being asked to do is so tedious, aversive, or difficult that being placed in time-out becomes a form of negative reinforcement (since it leads to the withdrawal of a stimulus that is even more aversive to them than time-out). Time-out may also be ineffective because the rewards that students can earn are not sufficiently powerful to induce them to avoid time-out, or the opportunities to earn

FIGURE 2. Sample home–school report card.

Child's Name: ______________________ Date: ______________________

Scoring: 4 = Outstanding
3 = Good
2 = Acceptable
1 = Improvement Needed
0 = Unacceptable

Completes his assigned work	0 1 2 3 4
Listens carefully to directions	0 1 2 3 4
Follows adult directions without arguing	0 1 2 3 4
Uses appropriate language	0 1 2 3 4
TOTAL POINTS EARNED	______

Comments:

rewards may be too limited. Whenever time-out is implemented, either at home or at school, it is a good idea to set up a reinforcement system first and to keep that system in place for a period of time before introducing time-out.

3. For some children, time-out is most effective when it is presented to the child not as a punishment but as a time for the child to "cool out" — to calm down, collect his or her thoughts, to do some relaxation exercises, and so on. Time-out then becomes an effective strategy to control anger. For this purpose, one can encourage the child to place him or herself in time-out voluntarily when it seems advantageous, rather than being sent by an adult.

Cognitive-Behavioral Interventions

Cognitive-behavioral interventions encompass many self-regulation strategies in which students learn to control their behavior by altering how they think about a task or situation. This section will address three approaches employed with youngsters with attention disorders.

Self-monitoring. These procedures involve training students to become aware of their own attending behavior, with the eventual goal being for them to cue themselves to attend. The most common training procedure is to employ an audio tape that sounds electronic tones at random intervals ranging from 15 to 90 seconds apart. When the tone sounds, students are instructed to ask themselves, "Was I paying attention?" Initially students are instructed to note their responses on a checklist. Eventually, they are weaned from both the checklist and the tape, but are instructed to note covertly whether they are attending. This approach has been demonstrated to increase attention to task (e.g., Hallahan, Lloyd, Kosiewicz, Kauffman, & Graves, 1979), and is a relatively easy intervention to introduce. It may be more effective when used as a whole-class procedure, since students sometimes feel singled out when such an approach is used individually. Self-monitoring tapes also can be employed effectively at home to increase attention to task during homework sessions.

Self-instruction. These procedures are more elaborate. Students are taught to "talk to themselves" as they perform a task. Self-instruction originally was developed as a strategy for helping impulsive children increase self-control through verbal mediation (Meichenbaum & Goodman, 1971). Numerous programs developed since have addressed both learning and behavior problems (see Wallace & Kauffman, 1986, for an overview of self-instructional strategies).

Self-instruction has been used with students with attention disorders to address problems with impulsivity, activity level, sustained attention, aggression,

FIGURE 3. Sample reinforcement menu.

Privileges	Cost
DAILY	
Extra half hour TV show	10
Extra snack	10
Practice soccer with dad	10
15 minutes video game time	10
WEEKLY	
Rent a video game	50
Rent a movie	50
Have a friend sleep over	60
Go out for ice cream	60
LONG TERM	
Go bowling	200
Earn a new cassette tape	200
Take a friend to a movie	300
Eat at a Chinese restaurant	300

compliance, and social skills. An example of a commercially available program designed to improve self-control is the *Think Aloud* program (Camp & Bash, 1981). With this approach, young children are taught to ask themselves four questions as they attempt cognitive or academic tasks: "What is my problem?" "How can I do it?" "Am I using my plan?" and "How did I do?"

Self-instruction also is employed to teach students social skills. A commonly used program is the *Skillstreaming* model developed by Goldstein and his colleagues (e.g., Goldstein, Sprafkin, Gershaw, & Klein, 1980). With this approach, children are taught specific skills in small, structured learning groups following a sequence of steps that includes skill definition, modeling, role playing, feedback, and generalization (via homework assignments and a token economy). While this model often is used in small group settings apart from the regular classroom, it can be more effective when whole classrooms participate in the process, led by the regular classroom teacher with assistance from a school psychologist, resource room teacher, or guidance counselor.

Another specific skill-instructional strategy that has some promising research support is correspondence training. With this approach, students are rewarded for achieving a correspondence between statements and behaviors — in other words, they are rewarded for doing what they say they are going to do. In one study, for instance, a young hyperactive, conduct-disordered boy was able to reduce inattention, overactivity, and noise as a result of correspondence training. He was given tangible reinforcers for making a verbal commitment, for following through on the commitment, and for consistent performance across observation trials (Paniagua, Morrison, & Black, 1990).

Self-evaluation. In this approach, students are taught to evaluate their progress on specific academic or behavioral goals — a simple example: a teacher would have reading group members rate how well they attended or how much they participated during the reading group session. Or teachers and students would separately rate targeted behaviors at the end of the day when a home-school report card is used, with subsequent discussion about agreement and disagreement of ratings.

Research has been somewhat equivocal about the effects of cognitive-behavioral techniques. Although clinicians have found them useful, the generalization of such methods to natural settings has been questioned, and their labor-intensive nature may make classroom use unrealistic (Fiore, Becker, & Nero, 1993).

However, questions have been raised as to whether cognitive-behavioral techniques can be sufficiently learned and successfully applied in the short amount of time most research studies employ. Developing a cognitive strategies curriculum that is taught over multiple years with collaborative efforts on the part of all teachers, such as the approach advocated by Deshler and his colleagues (Deshler & Schumaker, 1988) or the Benchmark program (Gaskins & Elliot, 1991) may be a more effective way to employ cognitive behavioral methodologies.

Parent Training

Often, just by becoming familiar with the characteristics associated with attention disorders, parents become more tolerant and accepting of their children and experience a reduction in stress which makes parenting easier and interactions between parents and children more positive.

Some parents, however, experience significant difficulty managing some of the more problematic behaviors of their children with attention disorders. They find that with younger children, compliance issues often are the most intractable, while with preadolescents and adolescents, setting limits and reasonable expectations for rights and responsibilities are of concern. Parent training to address these concerns is an effective approach that school psychologists can employ. With younger children, school psychologists may want to follow a model such as Barkley's *Defiant Children* (1987). This eight-week program follows a behavioral model, teaching parents to recognize and reinforce positive behaviors (including compliance with commands), to set up a home token economy, and to use time-out procedures appropriately both at home and in public. It can be used with individual families or with groups of parents. For older youngsters, school psychologists can train parents in negotiation strategies, such as those described by Robin and Foster (1989).

Parent training is most effective when it is one component of a multimodal approach to treating youngsters with attention disorders. It also enables school psychologists to develop nontraditional roles, strengthening the link between home and school.

Medication

Medication, primarily psychostimulants, is the most common treatment in this country for ADHD (Barkley, 1990). Stimulant medication also has been the subject of extensive research, concluding that "numerous studies have clearly demonstrated medication-induced, short-term enhancement of the behavioral, academic, and social functioning of the majority of children being treated" (Barkley, 1990, p. 573).

Although school psychologists are in an excellent position to monitor medication effects and to collect objective data that can help evaluate the efficacy of medication, they are sometimes in a difficult position with respect to recommending that parents consider medication as a possible treatment for ADHD. Parents often believe that school personnel advocate the use of medication as a way to avoid treating the behaviors of concern. When school psychologists evaluate youngsters for attention disorders, care should be taken to present the findings and recommendations to parents in such a way that medication is described as one of many possible intervention strategies. A decision regarding medication should be made by parents, in consultation with a physician experienced in treating youngsters with attention disorders. With teenagers, it is important to involve the youngsters themselves in making the decision about whether to use medication.

Medication should never be used as the sole treatment for ADHD, but should be employed in conjunction with other interventions. In most cases, other interventions, including behavior modification and classroom modifications, should be put in place before medication trials are begun. When this is done, the feedback mechanisms already developed to monitor the effectiveness of these interventions (e.g., points accumulated on a home-school report card) can be used to help evaluate medication effects as well.

Environmental Modifications

With appropriate modifications and accommodations, the educational needs of a majority of students with attention disorders can be met solely or primarily within a regular classroom environment. And while behavior modification strategies can be very effective in improving classroom performance and behavior, altering environmental variables and making task modifications are an important adjunct.

Research on task modifications for students with attention disorders has been conducted primarily by Zentall and her colleagues at Purdue University. Some of their findings that may be relevant to classroom settings are:

1. Stories presented at a faster-than-normal rate of speech resulted in improved listening comprehension and decreased activity level (Shroyer & Zentall, 1986).

2. Using color to highlight salient information increased accuracy and decreased activity level for students with ADHD (Zentall, 1985, 1986).

3. Tasks with a high degree of structure decreased activity level, compared to low-structured, more open-ended tasks (Zentall & Leib, 1985).

4. Active response (i.e., requiring a motor response) resulted in improved performance, compared to more passive response conditions (Zentall & Meyer, 1987).

5. Providing brief, global instructions, instead of lengthy, detailed instructions, produced shorter task completion time and fewer requests for cues (Zentall & Gohs, 1984).

6. Math and reading tasks presented in a low-noise environment created better performance and decreased activity levels than did a high-noise environment (Zentall & Shaw, 1980).

Effective classroom modifications include seating students preferentially, calling on the student fre-

quently during class discussions, writing start and stop times for written work completion, using a kitchen timer as a motivator, and providing the student with a daily checklist of assignments to help organize work assignments. Children with attention disorders, particularly if they have concomitant executive skill deficits, may need help getting started on assignments. This can be done by walking them through the first few items or talking to them about the assignment to help them get oriented. They often do significantly better when tasks are modified to respond to their deficit areas, including presentation of briefer tasks, building in breaks, allowing the opportunity to stand up and move around, and, as noted above, providing high within-task stimulation.

Other modifications for youngsters with ADHD address the fact that they tend to do best when they have frequent opportunities to respond and receive immediate feedback. Peer tutoring and cooperative learning approaches both build in greater opportunities for individual response and immediate feedback than do more traditional classroom structures, such as lectures and individual seatwork activities. Computers also offer great promise for youngsters with ADHD, because levels of response and feedback are increased and because computer software can be novel, entertaining, and interactive.

Modifications that address difficulty in written production include reducing writing requirements, allowing students to dictate or tape record assignments, and allowing for alternative means of demonstrating knowledge or learning, such as projects and oral reports. Providing access to computers to learn word processing and to complete written assignments is an essential modification for many youngsters with ADHD.

Still other modifications address the fact that youngsters with ADHD do more poorly with tasks they find tedious, difficult, or uninteresting. These modifications include reducing repetitive seatwork and making tasks and assignments as appealing as possible. Youngsters with ADHD respond very well to activities with a game format or to lessons that are presented as problems to be solved, particularly if they have real-life applications. Project-oriented learning is ideally suited to the learning style of many youngsters. Others respond to the opportunity to design their own assignments. Independent learning projects can be particularly effective at the secondary level. Allowing students to negotiate their own learning contract can increase motivation and enhance performance — another modification that may be especially effective at the secondary level.

Giving these students choices — in terms of *what* assignments they will do, *how* they will do them, *in what order, where*, and *with whom* they will complete the work — can have a dramatic impact on productivity and task completion. And pairing youngsters with ADHD with other students allows them to use complementary strengths. A youngster with ADHD may have very creative ideas but have trouble putting them down on paper, while another student may be skilled at organizing work and writing but lack imagination; by pairing the two, both can benefit — and learn — from the strengths of the other.

While we generally think about classroom and task modifications in terms of the learning weaknesses of youngsters with attention disorders, the strengths these students have must not be neglected. It is critically important for those who work with these students to identify their skills, aptitudes, and talents, to find ways to encourage their development, and to ensure that these students are recognized for their accomplishments. Youngsters with attention disorders tend to receive negative feedback in greater quantities than their classmates. Special efforts must counteract these threats to self-esteem by finding areas where these students can shine.

This is a brief summary of the kinds of instructional and task modifications that are employed frequently with youngsters with attention disorders. Figures 4 and 5 contain examples of other modifications that may be appropriate.

Support Services

While the interventions described above may be sufficient for most youngsters with attention disorders, others will require additional support services to meet their needs. Students with attention disorders may qualify for these services either through Section 504 of the Rehabilitation Act (which protects students who have a physical or mental impairment "that substantially limits one or more major life activities," such as learning) or through the Individuals with Disabilities Education Act, IDEA, through the disability category Other Health Impaired. Under Section 504, school districts develop an accommodation plan that defines what services are needed and how they will be provided. Under IDEA, these services are specified in the student's Individual Education Plan (IEP).

While the need for special education or other services is often determined on the basis of a discrepancy between scores on measures of ability and achievement, with children with attention disorders, the central issue is more often a problem with *daily classroom performance*, and it is on this basis that the need for services should be determined.

Support services, provided either through Section 504 or IDEA, may include any of the following:

1. A monitor with whom the student can check in one or more times a day. This approach often is employed at the secondary level, where students change classes and have many teachers, and may, as a result, have difficulty keeping track of assignments, materials, and possessions. A monitor helps ensure that the student hands in homework assignments, is prepared for class, and has the necessary materials for class participation and homework completion. Monitors can also help manage home-school report cards when they are used.

2. Supervised study halls, to ensure that students use this time wisely and can receive assistance with assignments as needed.

3. Help with study and organizational skills, either through tutoring, in a supervised study hall, or through participation in study skills courses. This may include assistance with setting up and keeping an assignment notebook, using memory aids, planning long-term assignments, monitoring progress on long-term assignments, and learning note-taking skills, time-management skills, and study and test-taking skills.

4. A classroom aide to help make task modifications, increase student time on task, intervene in response to disruptive behavior, and administer reinforcement systems.

5. Remedial instruction in areas of academic skill deficit.

6. Counseling services to address social/emotional needs, such as participation in social skills groups.

While these are all direct services, students with attention disorders are also entitled to indirect services, such as consultation for the classroom teacher from a special education teacher, counselor, or school psychologist.

Other Roles for School Psychologists

The school psychologist can play a critical role in designing appropriate interventions for students with attention disorders. Other roles that are well suited to the skills and training of school psychologists include:

1. Acting as a liaison among the home, the school, and other service providers, such as mental health workers and physicians.

2. Case managing, including follow-up to assess intervention effectiveness, data collection to monitor medication effects, and help with transitions to the next grade level, school, and the like.

3. Providing training and information to parents concerning the management of attention disorders in the home.

4. Providing in-service training for teachers.

5. Becoming involved with advocacy groups for parents of children with attention disorders. Besides becoming a valuable resource to such groups, this can have good public relations benefits for the school psychologist and the school district where he or she is employed.

SUMMARY

Youngsters with attention disorders present with a variety of characteristics that pose problems for school adjustment and academic performance. Familiarity with these characteristics, as well as other academic and social problems associated with ADHD, can help the school psychologist develop effective interventions. A problem-solving orientation, in which target behaviors are identified and interventions selected from an array of possible solutions, is well suited to the task of helping students with ADHD achieve success in school.

Possible interventions include modifying the beliefs and attitudes of those who work with students with attention disorders, modifying the environments in which these students live and learn, and modifying the behavior of the students themselves. Commonly used strategies include incentive systems, response cost methods, time-out procedures, cognitive behavioral strategies, parent training, psychopharmocological interventions, and modifying classroom environments, including instructional and task variables, both to address students' weaknesses and to enhance their strengths.

School psychologists play a vital role in meeting the needs of students with attention disorders. By working with schools to develop multimodal treatment plans, school psychologists can extend their traditional roles and put *all* their training and skills to work. And developing effective interventions for children with attention disorders may have the broader effect of helping schools become more responsive to the individual needs of *all* children. The kinds of strategies that help students with attention disorders can help other students as well. Accommodating the needs of children with attention disorders thus may help move us forward to a day when education can truly be personalized for *all* children.

FOOTNOTE

[1] The term ADHD is currently used to refer to all students with attention disorders. Although a significant number of students with attention disorders are *not* hyperactive, for ease of communication the term ADHD will be used in this chapter to refer to all students with attention deficit disorders.

ANNOTATED BIBLIOGRAPHY

Barkley, R. A. (1990). *Attention-deficit hyperactivity disorder: A handbook for diagnosis and treatment.* New York: Guilford Press.

This comprehensive volume addresses both diagnostic and treatment issues related to ADHD. It is perhaps the most comprehensive single volume addressing attention disorders and is highly recommended for all professionals who work with students with ADHD. The book is divided into three sections, with Part 1 addressing the nature and diagnosis of ADHD, Part 2 addressing assessment issues, and Part 3 devoted to treatment issues. Part 3 includes chapters on counseling and training parents, educational placement and classroom management, social skills and peer relationship training, and medication therapy.

Fiore, T. A., Becker, E. A., & Nero, R. C. (1993). *Research synthesis on educational interventions for students with ADD.* Research Triangle Park, NC: Research Triangle Institute.

This volume, prepared by one of the federally funded ADD Intervention Centers, contains a comprehensive summary of research on educational interventions for students with ADHD. Research is divided into seven topics: positive reinforcement, behavior reduction, response cost, cognitive- behavioral interventions, parent training, task/environmental stimulation, and biofeedback. For each topic area, the authors present a brief synopsis of research findings with suggestions for educators and areas for further study and a chart summarizing each research study reviewed. The rest of the volume consists of an annotated bibliography of the research studies.

Guevremont, D. C. (1992, Fall/Winter). The parents' role in helping the ADHD child with peer relationships. *CHADDER,* p. 17

This article, written for parents by an associate of Russell Barkley, outlines the social behaviors common to children with ADHD and then gives parents useful suggestions for improving social skills and enhancing their children's ability to make and keep friends. It describes a home reward program that is relatively easy to administer and goes on to suggest practical ways that parents can arrange for positive experiences with peers both at home and in the community. It concludes with suggestions for how parents may work with teachers to enhance social skills and positive peer interactions. It makes a useful handout that school psychologists can give to parents.

Teeter, P. A. (Guest Ed.). (1991). Mini-series: Attention-deficit hyperactivity disorders in children: Clinical and treatment issues. *School Psychology Review, 20,* 161–281.

This volume of *School Psychology Review* contains nine articles on a variety of topics associated with ADHD, written by the leading researchers in the field. In addition to articles on diagnosis and assessment, four articles address treatment issues. These include therapeutic effects of medication, classroom-based behavioral interventions, remediating social skills deficits, and training for parents of children with ADHD. Each of these articles provides a concise synopsis of current thinking and research as well as practical information the practicing school psychologist will find useful.

Best Practices in Early Intervention Design

David W. Barnett
Kristal E. Ehrhardt
University of Cincinnati

Early intervention has considerable promise but successful results are not guaranteed. The traditional model is based on the identification of children with disabilities followed by special class placements. However, outcomes of traditional special education services that stem from federal legislative efforts have been ambiguous at best and subject to extensive criticism. This chapter describes the basics of an alternative model for preschool children that is guided by intervention design principles.

OVERVIEW: THE FOUNDATIONS OF INTERVENTION DESIGN

The model for intervention design suggested in this chapter is based upon (a) ongoing problem solving involving parents and teachers and (b) intervention research. Consultation, suggested as the foundation for the provision of alternative educational delivery systems (Curtis & Meyers, 1988), provides a framework to guide the problem-solving process. Behaviors of importance include those interfering with parenting or teaching and ones precluding positive peer relationships. In addition, environmental characteristics and setting events may receive critical attention.

BASIC CONSIDERATIONS

Features of Parent and Teacher Consultation

Consultation is a process of collaborative problem solving between a consultant such as a school psychologist, parents, and/or other educational personnel such as a teacher (Curtis & Meyers, 1988). The consultation process generally includes problem definition and clarification, problem analysis, plan development, implementation, and evaluation. These stages or steps are not necessarily executed in lockstep order but are utilized as the situation demands.

Rather than providing direct services to children, the early intervention consultant engages in problem solving with primary caregivers to develop effective, acceptable intervention strategies for use within natural settings. Consultation goals are (a) the improvement of current problem situations through the development of effective interventions and (b) the prevention of future problems through the enhancement of the caregiver's and/or children's skills. Intervention strategies arising out of parent/teacher consultation may be developed for the home, community, and school, and are designed to support and expand skill development, generalization, and maintenance.

When guided by intervention design and a problem-solving model, those involved emphasize the identification of *problem situations*, not problem children. Problem situations are defined in terms of barriers or behaviors that preclude the natural effective roles of parents, siblings, teachers, and peers in children's development. Because the focus is on problem situations, from the outset it should be clear that caregiver behaviors, as well as the child's behaviors and setting characteristics, are frequently the focal points in problem solving. Thus, the unit of analyses are reciprocal interactions between child and caregiver behaviors and demands and expectations related to situations.

Making Sound Early Intervention Decisions

It is best if professionals involved in early intervention are oriented by an analysis of intervention decisions and outcomes and not by traditional educational classifications (Barnett, Macmann, & Carey, 1992). Establishing a goal of intervention design is supported by very different theory, research, and practice than those employed when establishing developmental delay or other "profiles" of developmental skills. Most important, intervention design is dominated by assumptions of change whereas diagnostic decision making is dominated by assumptions of stability. The basic frameworks for intervention decisions are reviewed in the following paragraphs.

1. Intervention design is guided by sequential rather than diagnostic strategies. *Sequential decision making* consists of identifying the most reasonable steps in the assessment-intervention process with

each step subsequently evaluated. Thus, most simply, sequential decision making yields responses to the questions "what is the most reasonable first step, second, step," and so forth, generated through problem solving. The steps address the what, where, who, when, and how of planning interventions — essentially a set of goals and a map of how to achieve those goals. Sequential decision making allows for continued reframing or refinement of target behaviors and interventions. While "diagnosis" may be used in some form (i.e., generalizations from research for a child described as autistic), it is not a primary goal for professional practices from the child's view — the goal is effective service delivery.

Sequential decisions are established by: (a) collaborative "team" problem solving (i.e., parent, teacher, and consultant), (b) logical and/or research-based steps in assessment-intervention design (i.e., establishing a baseline for preintervention behavior), (c) developmental studies of performance (i.e., social skills), (d) task analysis, and (e) decision-making "checks" to help ensure the adequacy of the overall plan and process.

Figure 1 includes checkpoints for features of the child's environments necessary for many intervention decisions. If not in place, a checkpoint may become a focal point for assessment and intervention design — and a prerequisite for subsequent steps. If a checkpoint cannot be "passed through," consultation focuses on problem solving to improve or restore the conditions or to assist with coping efforts. However, in some cases, as for example children raised in families inaccessible to the consultant, interventions may focus on available settings such as the classroom. In sum, rather than establishing developmental delay or another classification, the problem-solving steps are oriented to basic intervention decisions.

When developing an intervention, perhaps one of the most significant steps is to ensure that a nurturing caregiver is available to a child. For example, professionals may be serving very young children who may have been in numerous foster homes in their lives (our high is 11 homes for one young child in a 3-year period). Clearly establishing some stability in the caregiving environment is a top priority. Numerous temporary placements preempt normal learning opportunities, but we have seen children in these circumstances "tested" first to develop "plans" related to a disability. The analysis of quality indicators in a preschool classroom may be another important step in consultation. Such analysis should establish that the environment will support needed interventions and that the curriculum is developmentally appropriate and functional. If needed, organizational consultation can be arranged as part of the early intervention services.

2. Intervention design ultimately rests on *professional judgment*, but ironically formal techniques (behavior rating scales, developmental scales, IQ tests) used by professionals to objectify and help with the decision process introduce a wide range of errors that may be exceedingly difficult to detect. While space does not permit more than mention here, consultants should be aware of sources of potential error pertaining to specific assessment techniques, cognitive activities of professionals, and intervention design (Barnett et al., 1992). A good way to bolster professional judgment is to take significant care with *problem structuring*. While there are no panaceas, problem structuring is essentially building a collaborative understanding of a problem situation through interviews, observations, and logical generalizations from pertinent intervention research and from systematically evaluating plans. Because problem structuring must be developed from understanding natural interactions in natural settings, it cannot be built upon traditional developmental assessment or play-based assessment in contrived settings. Potential *intervention bias* is treated by creating a range of promising intervention alternatives (discussed in a subsequent section).

3. Intervention recommendations can result in radical departure from normal routines. As a guiding principle, *naturalistic intervention design* may be defined as identifying the least intrusive, most robust intervention that will accomplish the goals of change within a natural setting (see Yeaton & Sechrest, 1981). Naturalistic intervention design applies problem-solving steps toward identifying (a) naturally occurring parent or teacher intervention strategies likely to be successful either as implemented or with only minor changes developed through consultation and feedback and (b) research-based interventions adaptable to evident styles of parenting or teaching within a problem context and setting.

4. There are three significant educational issues inherent in early interventions and naturalistic design. First, *inclusion* is a philosophical stance used to help make judgments about the soundness of decisions for children based on normalcy of environments and activities. Basic premises are that services should be provided in normal settings and that the most normal interventions capable of accomplishing the goals of change are preferred.

Another basic consideration for early intervention is to ensure the *developmental appropriateness* of professional practices and outcomes (Bredekamp, 1987). Learning takes place within an interpersonal context whereby the caregiver's warmth and responsiveness are of critical significance. The caregiver's roles include creating learning environments, selecting learning events, focusing children's attention on those that are important, and by following the children's lead, encouraging children's curiosity and skill development.

FIGURE 1. Examples of decision-making checkpoints.

- Responsive and nurturing caregiver is available.
- Basic family needs aremet.
- Well-conducted developmental and functional curriculum is in place in a well-managed classroom.
- Child is adapting to classroom activities and routines.
- Child is progressing at satisfactory rate.
- Child has satisfactory relationships with peers.

A third core-educational issue is *transitional* planning. The preschool years are times of great change, and planning for change is a significant theme. Vincent and colleagues wrote: "Traditional special educational programming may be incompatible with child success in least restrictive programs" (1980, p. 326). Basic strategies include planning for the next environment by teaching children functional adaptive classroom skills (Sainato & Lyon, 1989) and helping parents with problem solving and planning.

BEST PRACTICES IN DESIGNING PRESCHOOL INTERVENTIONS

Assessment for Intervention Design

We recommend the use of ecobehavioral and functional analyses to gather assessment information necessary to design interventions. The goal of ecobehavioral analysis is the determination of functional relationships between independent and dependent variables within a broad ecological context (Greenwood, Carta, & Atwater, 1991). Thus, units of analysis are natural systems (e.g., families and classrooms), setting characteristics and events, behaviors, and their contingent variables (Rogers-Warren, 1984).

Functional analysis involves determining the relationship between specific behaviors and environmental factors that trigger or maintain them. Functional analysis is used to develop predictions about the conditions under which behaviors are likely to occur.

There are three basic techniques useful for early intervention design: ecobehavioral interviews, observations, and curriculum-based assessment. Adapted from Wahler and Cormier (1970), the waking-day interview provides a detailed description of behaviors across settings and problem situations for caregivers. The problem-solving interview is used to identify target behaviors and to examine problem situations in detail. Previously attempted intervention strategies are also explored.

A three-step process is effective in developing appropriate observations for home, preschool, or community settings.

1. The results of waking-day and problem-solving interviews are used to help define behaviors, places, circumstances, times for observations, and potential intervention roles.

2. Real-time observations are used to document target behaviors, interactions, situations, sequences of events, and possible naturalistic interventions. This observational technique focuses on a child's behaviors, interactions, and situations. The observer records meaningful and complete units of behaviors in lines or sentences and records the clock time for each unit of behavior. A brief example follows.

11:12 Begins play alone at water table.
11:13 Approached by another child.

Data collected from real-time observations can yield frequency of behavior, rate of occurrence, duration, prevalence, and interresponse time.

3. Decisions are made about the use of other observation techniques based on findings from interviews and real-time observations. Relatively high-rate behaviors or those related to parent—child or teacher—child typically will benefit from consultant observation and perhaps from the use of a preschool observation code (e.g., Bramlett & Barnett, 1993), or an A-B-C (antecedent-behavior-consequence) analysis. Low-rate behaviors (i.e., infrequent tantrums, fire setting) usually require that parents or teachers serve as the primary observers. Observation techniques useful for preschool settings are described in more detail by Wolery (1989).

Criticism of traditional developmental assessment pertain not to the importance of developmental objectives but to how the skills are measured. Curriculum-based assessment enables ongoing observations of children's performance in preacademic, social, and other developmental areas and yields information needed to determine the conditions necessary for competent performance. Although not free of measurement problems, curriculum-based assessment involves the analysis of functional developmental skills within an instructional context.

Selecting Likely Interventions

Preschool consultants are usually needed, not to identify a specific intervention, but to expand the range of interventions that may be considered by parents and teachers. Thus, a fundamental question is "Where do we get intervention ideas?" Interventions are (a) generalized from developmental studies and intervention research, (b) founded on the realities of settings determined through problem analysis, and (c) based on the predicted success of the least intrusive intervention likely to accomplish the goals of change. Examples of well-established and promising research-based interventions are summarized in the following paragraphs.

1. *Fundamentals.* Simple, basic, and well-researched interventions should be considered before more obscure, radical, intrusive, or expensive interventions. In our work with Head Start children, the following interventions have been used extensively. While they may seem commonplace, they serve as a starting point for analysis and as foundations for intervention design for many preschool children across diverse problem situations for ethical and practical reasons.

   a. *Environmental enrichment, responsiveness, and monitoring:* Preschool psychologists may do well by assisting with ways to enhance "time-in" environments, and rule development and management procedures so that children may fully experience them.

   > An enriched environment . . . provides availability of and reinforcement for interacting with materials and activities, opportunity and reinforcement for the use of language and other forms of communication, a high interest curriculum, novelty in available stimuli, frequent reinforcement for adaptive behaviors, opportunities for structured and incidental social interaction, an adequate amount of personal space, choices within a predictable schedule, and the opportunity for community participation. (Schrader & Gaylord-Ross, 1990, p. 408–409)

   Responsiveness is a significant broad construct in early intervention research and generally pertains to caregiver attentiveness and interactions resulting from children's communication attempts. From the child's view, it is a feature of an enriched environment. Effective parents and teachers scan and monitor behavior with intensity appropriate for the child and task. These skills, responsiveness and monitoring, within an enriched environment, are keystones of intervention design.

   b. *Rules and consequences:* Rule learning is essential for self-regulation as well as family and classroom management. The basic principle is that carefully selected, positively stated, learned, and enforced rules establish expectations for behavior. Paine at al. (1983) provided a thorough discussion about setting up classroom rules that we have frequently used and have adapted for many parent consultations.

   c. *Differential attention:* Differential or systematic attention consists of approval contingent on desired behavior. It may be used to shape new behaviors and maintain or generalize behaviors. By definition, it is brief and may be nonintrusive. However, this intervention may be easily squandered or misapplied. Furthermore, studies show that appropriate behavior is frequently and inadvertently ignored and misbehavior may actually be rewarded. Thus, assessing caregivers' use of differential attention is often a necessary step for intervention design. Assessment for differential attention may be conducted through an A-B-C analysis.

   d. *Modeling and opportunities to practice:* According to Bandura (1986), most behavior is learned through modeling. Thus, modeling appropriate and adaptive behavior and guiding, prompting, and reinforcing children to perform new or alternative behaviors are basic intervention strategies.

   One of the most powerful interventions for preacademics or social behavior is simply increasing "opportunities to practice" skill attainment (Greenwood, Delquadri, & Hall, 1985). Two steps are necessary: (a) analyzing occasions for learning and practice, and (b) increasing the chances for practice and feedback.

   e. *Reprimands:* Children referred for behavior or learning problems may be experiencing very negative environments. Reprimands (and more harsh forms of discipline) are frequently overused and ineffective, and thus may be a critical point of consultation. We recommend routinely asking parents making referrals about misbehavior to describe their use of discipline and their feelings about it. One of the additional benefits of consultation regarding the ineffective use of reprimands is to improve family environment. However, if it is likely that reprimands will be used because of parental preference, we recommend procedures by Van Houten (1980) in addition to increasing positive experiences.

2. *Reducing maladaptive behaviors (including excessive activity changes) and increasing adaptive behaviors.* Back to the idea of "check-

points": All of the above interventions (time-in, rule development and implementation, etc.) constitute "gates" for referrals related to misbehaviors. In other words, children would not be referred, assessed, and labeled as behavior disordered, ADHD, or learning disabled (or other similar labels); rather, consultation would first occur to ensure that fundamental features of a supportive environment are in place. If environments are sound and maladaptive behavior continues, further intervention planning is in order. The next section gives examples of other techniques with the goal of expanding the range of intervention alternatives.

a. *Behavioral momentum:* Interventions need appropriate strength or power to accomplish desired change. Behavior momentum refers to the resistance of behavior to change. Resistance must be analyzed by behavioral factors (severity, chronicity, generalization, and teacher/parent tolerance of behavior) and intervention factors (strength of intervention, acceptability, treatment integrity, competing contingencies of reinforcement, and treatment effectiveness). Davis, Brady, Williams, and Hamilton (1992) give a simple example (and background references for those interested). They used high-probability commands — those likely to be complied with based on a child's history — like "touch your nose" to increase behavioral momentum of responding that would carry over to low-probability commands such as "pick up your toys."

b. *Teaching alternative responses and functional communication training.* Extending the discussion of differential reinforcement (related to differential attention, above), there are many positive intervention procedures to reduce maladaptive behaviors. Differential reinforcement means that certain responses are reinforced while others are not. (Because the procedures build on changes in reinforcement patterns, a functional analysis, discussed earlier, is a prerequisite.) "Differential reinforcement of alternative behavior" means a more acceptable behavior is substituted for the maladaptive behavior and occurrences of the acceptable behavior are reinforced. A common example is play engagement as an alternative for unoccupied time. Alternative responses may need to be first taught and practiced.

   Carr and Durand (1985) argued that communication skills may offer significant possibilities as functional alternative skills for severe problem behaviors. They proposed a "communication hypothesis of child behavior problems" where behavior problems function as "nonverbal communication acts" (p. 124). Durand (1990) presents a detailed guide for professionals to assist with functional communication training.

c. *Differential reinforcement of diminishing (DRD) rates of behavior:* This tactic means that reinforcement is contingent on a preplanned reduction in response rate (Sulzer-Azaroff & Mayer, 1991). Two examples should make it clear why this contingency arrangement may be valuable. A mother may be concerned with excessive yelling or the use of intense reprimands that occur with very high frequency. She may "self-reward" at the end of the day if self-monitoring demonstrates that 17 "yells" were recorded, down from 18 the day before. As another example, a child may show 10 "complaints" in play with other children; a decrease to 9 "complaints" is reinforceable during the next play period. Thus, on subsequent days, the mother and child in our examples would have to beat the prior days' accomplishments to be reinforced. Goal setting is critical (i.e., realistic goals for "yelling" should be established). DRD may be used for eliminating behaviors or reducing behaviors to suitably low levels. As with other differential reinforcement strategies, an important condition is that appropriate alternative behaviors need to be in the person's repertoire or must be taught.

d. *Intervention "packages" for parents and noncompliant children:* The term "package" in this context applies to a multicomponent intervention with strong evidence for wide applicability. Many parents have been referred to us for behaviors typically described as conduct disordered or oppositional. Earlier, we described work by Durand (1990) that falls under this category. Another intervention "package" is provided by Barkley (1987). Sanders and Dadds (1993) also provide a comprehensive model for parent consultation.

3. *Teaching language in natural settings.* Language and communication referrals are pervasive in preschool settings. Perhaps the best example of a naturalistic intervention is incidental teaching in facilitating language development (Warren, 1992). Incidental teaching capitalizes on important exchanges between a child and caregiver in relatively unstructured settings rich in materials or activities. The adult, following the child's lead, focuses attention on the child's verbalizations and encourages elaboration. The power of incidental teaching results from the

cumulative effects of numerous brief exchanges between child and caregiver (or siblings, peers).

Tirapelle and Cipani (1991) described an intervention termed a *missing-item format* that employs both incidental teaching and brief time-delays. Teachers provide opportunities to practice and motivation to do so by removing a necessary item from a natural activity. For example, in a game-like fashion, the spoon or cereal may be briefly removed giving the child an opportunity to make a functional request. Correct responses are prompted after an incorrect response or a delay of 5 seconds.

4. *Teaching functional skills.* Early intervention is not only concerned with the remediation of problems, but also involves enhancing child development through teaching functional skills. Bricker and Cripes (1992) proposed an activity-based approach to early intervention combining strategies from applied behavior analysis, early childhood education, and naturalistic intervention design.

5. *Intervening with groups and peers.* There are many significant reasons for considering environments, groups, and peers as targets for intervention efforts. First, "when a group is functioning well, it is extremely difficult for an individual child to behave in a disturbed way" (Hobbs, 1966, p. 1112). Second, environments may be changed to help support appropriate behaviors. Examples include availability of play materials and planning of play areas to help promote social, adaptive, and educational goals, or planning transitions between activities. Third, interventions related to social competence must have a social context such as play and sharing. Groups of children and peers may add power to intervention efforts by providing models for skills and behaviors and significant reinforcement for learning, generalizing, and maintaining behaviors. Odom and associates (1988) present a curriculum dedicated to these efforts.

Determining Reinforcement Preferences and Strategies

Reinforcers are contingent *events* that follow a response and increase the likelihood of further occurrence of behaviors in the same *response class.* Thus, reinforcers are defined by effects on behavior. The idea of a response class is critical because complex interrelated behaviors are typically the unit of analysis (i.e., whining, throwing, tantrums, crying following a parent request). Due to space limitations, discussion of types and schedules of reinforcers will be omitted. Rather, readers are referred to basic texts such as Sulzer-Azaroff and Mayer (1991).

Multiple assessment methods should be used to assess reinforcement preferences including interviewing teachers and parents, and observation. We concentrate on research-based strategies for selecting positive reinforcers for young children that build on direct observations. A general principle is to select the most natural reinforcer, and ideally the most subtle, that is effective for a problem behavior and situation. A basic strategy is functional analysis leading to rearrangement of contingencies for events that follow behavior.

Adding something to situations may frequently be necessary. The "something" can involve material reinforcers; social reinforcers ("Hugs," "Great," "Thank you for __________", which have added information value); or activity reinforcers which may be very potent and under natural teacher and parent control. In some cases, a set of strategies that stem from *reinforcer sampling* may be effective. A child can be given several samples of reinforcers, and preferences can be observed directly. Furthermore, reinforcement value may be increased by seeing other children play with the object.

An additional consideration is that children habituate to reinforcers. Mason, McGee, Farmer-Dougan, and Risley (1989) developed methods for *ongoing assessment of reinforcer preferences* that capitalize on novelty and variety — two other critical dimensions. Thus, choice making may be an important added component.

In considering other reinforcement strategies, do not forget *Grandma's Law* (Premack Principle): High-frequency behaviors (playing with favorite toys) are made contingent on low-frequency behaviors (completing preacademic task). Although it has a wicked sounding title, the *response deprivation hypothesis* is simply a more general statement of Grandma's Law and has may possibilities for reinforcer assessment: Almost any behavior in which children naturally engage in may be a potentially effective reinforcer, "proving access to that response can be restricted" (Sulzer-Azaroff & Mayer, 1991, p. 160). In fact, a low-probability behavior can function as a reinforcer for a high-probability behavior if there are restrictions placed on responses as assessed at baseline levels. Stollar, Dye-Collins, and Barnett (1994) reduced the inappropriately high activity levels of two children by placing some mild restrictions (and rules) on free play. Last, it is important to evaluate the reinforcement context. There may be competing contingencies and concurrent reinforcers that diminish intended reinforcer effects (Herrnstein's "Law of Effect"). Durand (1990) has an excellent section of identifying reinforcers.

Evaluating Preschool Interventions

Acceptability. Acceptability refers to judgments by caregivers regarding the appropriateness, fairness,

FIGURE 2. Script for redirection to appropriate activity and differengial attention.

Mark (Y) for yes, (N) for no, or (DN) for didn't need after each step below.

Steps	Date					
	Time					
1. Scott begins inappropriate activity						
2. Mom tells Scott "Don't do ________________."						
3. Mom redirects him to an alternative activity, "Scott come here and play with this truck.						
4. Mom begins to play with toy. "Look how fast this blue truck goes."						
5. Scott plays with the truck.						
6. Mom praises Scott's appropriate play. "I like it when you sit quietly and play with the truck."						
7. If Scott continues inappropriate activity, Mom gives him a warning. "If you don't stop that, then you are going to sit in the chair."						
8. If Scott does not comply, Mom uses script for time out.						

reasonableness, intrusiveness, and normalcy of interventions (Kazdin, 1980). A purpose for evaluating acceptability is to anticipate and avoid rejection of an intervention and to provide information about variables that affect a consumer's use of an intervention.

Treatment integrity. Treatment integrity is the degree to which an intervention is carried out as planned (Yeaton & Sechrest, 1981). Achieving a high degree of treatment integrity is critical to ensuring intervention effectiveness. Many failures in interventions may be attributed to a lack of treatment integrity. Without assessment and monitoring of treatment integrity, any interpretations about the effectiveness of interventions are questionable.

Several factors may affect treatment integrity of interventions (Yeaton & Sechrest, 1981), including: (a) complexity of treatments, (b) time required to implement interventions, (c) materials/resources required, (d) number of treatment agents, (e) perceived and actual effectiveness, and (f) motivation of treatment agents. Also, interventions that require expensive materials, substantial changes in the classroom or home ecology, and/or atypical privileges may not be readily implemented. In sum, the more complex and time-consuming the intervention, the less likely that it will be implemented as intended. Conversely, naturalistic interventions may have greater treatment integrity because they are based upon existing caregiver competencies.

Scripts can be used as treatment integrity measures. Essentially they are personalized and detailed guidelines (written or pictorial) for providing instructions and/or managing behaviors to meet specified goals. Scripts are developed through collaborative consultation with caregivers using information from ecobehavioral interviews and/or real-time observations about interactions, naturalistic interventions, and goals. An example of a script is depicted in Figure 2.

Evaluating intervention outcomes. Evaluation is a continuous process that includes judgments of how reasonable the interventions are, whether they are sufficiently powerful to lead to desired changes, whether they are being carried out as planned, and whether they lead to desired changes. The adequacy of intervention design is determined at the individual-case level.

Single-case experimental designs are particularly appropriate for evaluating the effectiveness of individual interventions in professional practice (Barlow, Hayes, & Nelson, 1984). These designs emphasize repeated, ongoing measurement, and modification based upon data analysis. A critical feature of single-case design is that it provides measures of level, trend, and stability of behavior across baseline and intervention phases. Typically, these types of data are presented graphically and analyzed visually to determine intervention effectiveness or the need for modification.

CONCLUSIONS: MEETING PRESENT AND FUTURE FEDERAL GUIDELINES

Recent federal legislation (PL 99-457 amended by PL 101–476) attests to the importance of early intervention. However, intervention design builds on a collaborative problem-solving process, not disability evaluation. Interventions must be well conceived and well executed and linked to key adaptive and developmental outcomes. Children who remain at a particular level of a skill sequence, who have problems with rate of skill attainment, or who continue to exhibit behavior problems, may require a change in instructional and/or intervention strategies to progress adequately. If the child still has difficulty with progress, a "decision" should be made to provide additional consultation and more intensive measurement and intervention efforts. Following consultative services and well designed interventions, the children still not meeting goals may be described as resistant to intervention efforts and may be in need of special services. Specific plans (currently defined as IFSPs and IEPs) and additional resources to assist teachers and parents may be necessary.

Best Practices in Preschool Social Skills Training

Stephen N. Elliott
Caroline N. Racine
R. T. Busse
University of Wisconsin–Madison

OVERVIEW

Developing skills for successful social relationships is one of the most important accomplishments of childhood. This interpersonal social process, although not fully understood, begins soon after birth and is influenced by personal variables (e.g., physical abilities, language, and communication skills) and environmental variables (e.g., family members' and peers' involvement and interactions). Unfortunately, not all children acquire adequate social skills and consequently, often experience negative child–adult or child–child relationships. Thus the identification and treatment of preschool children who are experiencing delays or deficiencies in social-emotional development warrant the attention of teachers, parents, and psychologists. This call for attention is congruent with recent research, which documents significant social skills deficits in young students with mild disabilities (Guralnick, 1986; Strain, Odom, & McConnell, 1984). Briefly, this literature indicates that students with disabilities frequently display fewer positive social and cooperative behaviors, show less initiative in peer interactions, and exhibit lower rates of peer reinforcement than their nondisabled peers. If untreated, these social skills deficits may remain relatively stable over time, be related to poor academic performance, and be predictive of social adjustment problems in adolescence and adulthood (Parker & Asher, 1987). Given these concerns, psychologists and educators are encouraged to include methods of assessing and treating social skills in their daily activities.

The purposes of this chapter are (a) to provide an overview of normal social development during the preschool years and the behavior expectations of adults for preschool children; (b) to briefly review the process of assessing social skills and identifying children in need of treatment; and then (c) to focus on practical assumptions and effective methods for promoting social skills in preschoolers. (Readers interested in more information on these topics are referred to the Annotated Bibliography at the end of this chapter.)

BASIC CONSIDERATIONS

Identification and Development of Socially Important Behaviors

Behaviors such as sharing, helping, initiating relationships, requesting help from others, giving compliments, and saying "please" and "thank you" are socially desirable behaviors that almost everyone would agree are examples of social skills. In general, social skills may be defined as socially acceptable learned behaviors that enable a person to interact with others in ways that elicit positive responses and assist the person in avoiding negative responses (Gresham & Elliott, 1984). When social skills are enacted successfully, the reactions generally are positive perceptions of social competence.

The acronym CARES has been offered by Gresham and Elliott (1990) to facilitate identifying and remembering five major behavioral clusters of social skills. These clusters are Cooperation, Assertion, Responsibility, Empathy, and Self-Control. Briefly, these clusters of social behaviors can be characterized for preschoolers as follows:

1. Cooperation — behaviors such as helping others, sharing materials with a peer, and complying with rules.

2. Assertion — initiating behaviors such as asking others for information and behaviors that are responses to others' actions such as responding to peer pressure.

3. Responsibility — behaviors that demonstrate ability to communicate with adults and concern about one's property.

4. Empathy — behaviors that show concern for peers' or significant adults' feelings.

5. Self-Control — behaviors that emerge in conflict situations such as responding appropriately to teasing or to corrective feedback from an adult.

Guevremont (1990) developed an alternative, but equally appealing, situational approach to characterizing clusters of target skills. Specifically, these skill clusters are referred to as social entry skills, conversational skills, conflict-resolution and problem-solving skills, and anger-control skills. Regardless of the terminology or approach one uses to characterize target behaviors, the behaviors of interest to most individuals conducting social skills interventions are those overt nonverbal and verbal interpersonal skills that maximize social engagement and social reinforcement.

What is the normal course of the development of social skills in young children? There is general agreement that older preschool children engage in socially cooperative activities with greater frequency than younger children. Having established the general agreement that social interaction does indeed increase ontogenetically, with interactive behaviors occurring very early in a child's life, investigators have directed attention to the behavioral components of successful social interactions. Findings from these investigations are relevant to efforts to remediate social skills deficits in children who have difficulty interacting effectively (cf. Eisenberg & Harris, 1984).

One area of interest concerns social initiation, that is, the manner in which a child attempts to initiate social interaction. Leiter (1977) found that requests to play accompanied by whining, crying, begging, or coercion were more likely to be denied; whereas, friendly, smiling initiations with suggestions for an activity were more likely to be accepted. This is not to say that children who are ingratiating always have successful social initiations. Rather, a judicious balance between assertiveness and accommodation to others' interests constitutes a more successful strategy (Lamb & Baumrind, 1978). Similarly, Hazen, Black, and Fleming-Johnson (1984) found popular children who were successful at entering others' play situations were able to flexibly alter their entry communications to fit the demands of ongoing play situations, which reflected not only the children's knowledge of a wide array of social initiation strategies but their adaptability in using the strategies appropriately. Further, in contrast to less socially successful children, popular children clearly indicated the children to whom they were addressing their entry statements, and they communicated to all children in the play situation they were trying to enter. It is apparent, then, that successful social initiation is characterized by specific nonverbal and verbal communication behaviors that clearly transmit the entering child's desire as well as awareness of contextual accommodations.

A second area of relevant developmental research is concerned with those skills that enhance the maintenance of social interaction. Asher (1978) describes the characteristics of the maintenance skills that are frequently used by socially successful children. These include complex perspective-taking abilities, such as adjusting the effectiveness of one's communications to other children's needs. In addition, more straightforward reinforcement strategies may be employed, such as offering other children praise and approval, as well as going along with another child's plan or wishes. Related to these maintenance skills is the manner in which interpersonal conflict is managed by children who exhibit successful interaction styles. In a study of preschool children's friendships, Hartup, Laursen, Stewart, and Eastenson (1988) found that conflicts among friends did not differ from conflicts among nonfriends in situational inducement, frequency, or duration. What did make conflicts distinct between friends and nonfriends was an effort to maintain the interaction with friends in spite of the disagreement. The children who were friends accomplished this by disengaging from each other temporarily, which served to reduce the intensity of the conflict and increased the likelihood of parity in outcome. This study exemplifies efforts to understand social skills within the context of perspective-taking. That is, behaviors that comprise successful peer interactions may be conceptualized as reflective of a maturing social-cognitive system in which children are developing the abilities to consider and coordinate their and others' points of view (LeMare & Rubin, 1987).

Whereas the above brief review illustrates some highpoints in the development of social skills, it does not address an additional issue of interest in the remediation of social skills deficits in preschool children, that is, the behaviors of young children. It is important to consider this issue, since an intervention program that addresses socially valid target behaviors and establishes goals has a greater chance of being used and maintained (Elliott, 1988). In a recent investigation, Elliott, Barnard, and Gresham (1989) asked the teachers and parents of a heterogeneous group of preschool children to rate the frequency and importance of over 50 discrete social behaviors from the Social Skills Rating System (SSRS). The collective ratings of parents indicate that they considered the following five social skills the most important for their preschool children at home: (a) requests permission before leaving the house, (b) reports accidents or minor emergencies to an adult, (c) shows concern for friends' and siblings' feelings, (d) pays attention to parent verbal instructions, and (e) communicates problems to a parent. Thus parents of preschoolers seem to place high value on basic communication skills and behaviors that indicate respect for others. For the teachers of these children, the following were the social skills of greatest importance for functioning in their classrooms: (a) attends to teacher's instructions, (b) complies with teacher's directions, (c) appropriately asks questions of the teacher when unsure of what to do in schoolwork, (d) finishes class assignments within time limits, and (e) cooperates with peers without prompting from the teacher. These teacher-valued social behaviors are indicative of compliance, cooperation, and orderliness.

Assessment of Social Skills and Identification of Children in Need of Social Skills Training

A number of methods, including rating scales, checklists, and sociometric nomination techniques, have been designed to identify children at risk for behavior problems. In general, the social skills assessment technology for preschoolers is not well developed. For example, there is only one published social skills rating scale (i.e., Social Skills Rating System) designed for use with preschoolers. Reviews of social skills assessment methods have been published by Gresham and Elliott (1989), Strain, Guralnick, and Walker (1986), and Demaray et al. (1993).

In general, the purposes of social skills assessments concern either identification/classification or intervention/program planning. From a behavioral perspective, the critical characteristic that differentiates assessment methods is the extent to which a method allows for a functional analysis of behavior (i.e., the extent to which an assessment procedure provides data on the antecedent, sequential, and consequent conditions surrounding a molecular behavior).

Process of assessment. As with the psychological assessment of any problem, the process of social skills assessment can be characterized by a series of hypothesis-testing sequences. Hypotheses are generated in an attempt to answer questions regarding identification, intervention, and evaluation of treatment effects.

A standard battery of tests or methods for assessing social skills does not exist. Rather, hypotheses generated dictate the direction of assessment, the questions to be answered, and the methods to be used. Assessment should proceed from global to specific to allow for appropriate planning of interventions. In contrast, evaluation of intervention success typically proceeds from behavior-specific outcomes to more global analyses of important social outcomes.

Ideally, practitioners should use assessment methods that possess the attributes of reliability (i.e., consistency of measurement), validity (i.e., capability of answering a given assessment question), and practicality (i.e., costs of collecting information). Unfortunately, few social skills assessment methods meet all of these criteria. Easily administered instruments that are useful for screening purposes generally are of little help in designing interventions. Other methods that require considerably more effort from assessors and clients (e.g., naturalistic observations and self-monitoring) often have equivocal or unknown psychometric properties (Dodge, Murphy, & Buchsbaum, 1984; Gresham & Elliott, 1984). Moreover, there is a tendency for assessment data obtained from different sources to correlate moderately at best: often their correlation is quite low (Achenbach, McConaughy, & Howell, 1987). Still, as a safeguard, multiple sources of information are considered a best practice when assessing social skills.

To increase the likelihood of accurate identification and classification of social behavior problems, we recommend the use of direct observations of the target child and nontarget peers in multiple settings; behavioral interviews with the referral source and possibly the target child; rating scale data, preferably norm-referenced, from both a social skills scale and a problem behavior scale completed by the referral source; and sociometric data from the target child's classmates. Regarding intervention decisions, data contributing to a functional analysis of important social behaviors are imperative. These types of data usually result from multiple direct observations across settings; behavioral role-plays with the target child; and teacher and parent/guardian ratings of socially valid molecular behaviors. Behavioral interviews with the treatment agent(s) also will be important for assessing the treatment setting, the acceptability of the final treatment plan, and the integrity with which the plan is implemented. Table 1 provides a summary of an heuristic sequence for the assessment of social skills.

Basic Assumptions and Procedures for Linking Social Skills Assessments to Interventions

Social skills interventions focus on positive behaviors and most often use nonaversive methods (e.g., modeling, coaching, and reinforcement) to improve children's behavior. These also are the characteristics that teachers and parents report they like in interventions (Elliott, 1988). Therefore, use of these methods may enhance treatment acceptability and integrity. In addition, these programs can be built into the existing structure of a classroom or home environment, thus minimizing the time required for successful implementation and maximizing treatment generality. Finally, social skills interventions can be used with individuals or groups of students, and because they primarily concern increasing prosocial behaviors, all students can participate and benefit from the interventions.

The selection of social skills interventions rests heavily on the classification of social skills difficulties as resulting from either deficits in response acquisition or response performance (e.g., Bandura, 1977).

TABLE [illegible]
Overview of Social Skills Assessment Methods and Their Characteristics

1. Teacher Ratings of Social Skills
    - A. Estimation of frequency of behaviors
    - B. Estimation of behavior's importance to teacher
    - C. Tentative estimation of skill and performance deficits
    - D. Guidance for teacher interview and direct observations
2. Parent Ratings of Social Skills
    - A. Estimation of cross-setting generality of deficits
    - B. Parent's perceived importance of social behaviors
    - C. Guidance for parent interview
3. Teacher Interview
    - A. Further delineation of target behaviors
    - B. Functional analysis of behavior in specific situations
    - C. Selection of target behaviors based upon importance ratings and teacher's rankings
4. Parent Interview
    - A. Further delineation of target behaviors
    - B. Functional analysis of behavior in specific situations
    - C. Selection of target behaviors based upon importance ratings and teacher's rankings
5. Direct Observations of Classroom Behavior
    - A. Functional analysis of behavior
    - B. Direct measurement of behavior in applied setting
    - C. Observation of peer reactions to target child's behavior
6. Sociometrics Using Liked Most and Liked Least Nominators
    - A. Measurement of social preference and social impact
    - B. Classification of sociometric status (rejected, neglected, controversial)
7. Self-Report of Social Skills — Obtain Child's Perception of Social Behavior
8. Child Interview

Note. Adapted from Elliott, Sheridan, and Gresham (1989).

Gresham and Elliott's (1990) Social Skills Rating System extended this two-way classification scheme to include areas of social skills problems, social skills strengths, and potential concurrent interfering problem behaviors. As shown in Figure 1, this scheme distinguishes whether a child possesses the ability to perform a target skill and whether interfering behaviors (e.g., aggression, anxiety) are present. Additionally, Figure 1 includes suggested treatments that have been found effective for various problem types.

Social skills acquisition deficits. This social skill problem characterizes children who have not acquired the necessary social skills to interact appropriately with others, or children who have not acquired a critical step in the performance of a given skill. Training in skill acquisition frequently uses direct treatment approaches, such as direct instruction, modeling, and coaching.

Social skills acquisition deficits with interfering problem behaviors. This social skills problem describes children with responses that interfere with skills acquisition; these responses can be emotional (e.g., anxiety, sadness, impulsivity) and/or overt behavioral (e.g., verbal or physical aggression, tantrums, excessive movement). Thus, with social skills acquisition deficits accompanied by significant interfering behaviors, the intervention objectives are to teach and increase the frequency of prosocial behaviors while concurrently decreasing or eliminating interfering problem behaviors. Interventions designed to remediate emotional responses typically involve emotional-arousal reduction techniques such as desensitization or flooding, paired with self-control strategies such as self-talk, self-monitoring, and self-reinforcement (Kendall & Braswell, 1985; Meichenbaum, 1977). Interventions that can help reduce overt behaviors often are referred to as reductive procedures (Lentz, 1988). These procedures include the use of differential reinforcement (e.g., differential reinforcement of other behavior [DRO], differential reinforcement of alternative behaviors [DRA], and differential reinforcement of low rates of responding [DRL]), group contingencies, and mild aversive techniques (e.g., reprimands, time out from positive reinforcement, response cost, and overcorrection). If

FIGURE 1. A classification schema for conceptualizing and linking social behavior problems to interventions.

	No interfering problem behaviors	Interfering problem behaviors
Social skills acquisition deficits	Direct instructon Modeling Behavioral rehearsal Coaching	Modeling Coaching Differential reinforcement of a low rate of response (DRL) Differential reinforcement of other behavior (DRO) Reductive procedures to decrease interfering problem behaviors
Social skills performance deficits	Operant methods to manipulate antecedent or consequent conditions to increase the rate of existing behaviors.	Operant methods to manipulate antecedent or consequent conditions to increase the rate of existing prosocial behaviors Differential reinforcement of a low rate of response (DRL) Differential reinforcement of other behavior (DRO) Reductive procedures to decrease interfering problem behaviors
Social skills strengths	Reinforcement procedures to maintain desired social behavior Use student as a model for other students	Reinforcement procedures to maintain desired social behavior Reductive procedures to decrease interfering problem behaviors

aversive techniques are used, it is a best practice to couple aversives with socially positive procedures.

Social skills performance deficits. Children with social skills performance deficits have appropriate social skills in their behavior repertoires, but do not perform the behavior at acceptable levels, at appropriate times, and/or in appropriate settings. Interventions for social skills performance deficits typically use manipulations of antecedent and consequent contingencies such as peer initiations, social reinforcement, and group contingencies.

Social skills performance deficits with interfering problem behaviors. Children with social skills performance deficits accompanied by interfering problem behaviors have acquired given social skills, but performance of the skills is hindered by emotional or overt behavior responses and by problems in antecedent or consequent control. Self-control strategies to teach inhibition of inappropriate behavior, stimulus control training to teach discrimination skills, and contingent reinforcement to increase display of appropriate social behavior often are used to ameliorate this social skills problem. Occasionally, when the interfering behaviors persist, it may be necessary to use reductive methods in addition to positive techniques.

Social skills strengths. Many children exhibit social skills strengths that often may be overlooked and may be undermined through lack of attention. Therefore, it is a best practice to take a proactive approach to maintaining those strengths through reinforcement of desired social behaviors. Children with strong social skills also can become part of a treatment strategy for children with social skills deficits by serving as models or as participants in peer pairing and peer initiation strategies.

Procedures for Promoting Social Skills

Teaching children social skills involves many of the same methods as teaching academic concepts. Effective teachers of both academic and social skills model correct behavior, elicit an imitative response, provide corrective feedback, and arrange for opportunities to practice the new skills (Cartledge & Milburn, 1986; Elliott & Gresham, 1991). A large number of intervention procedures have been identified as effective for social skills training with preschool children. These procedures can be classified into three approaches that highlight common treatment features and assumptions about how social behavior is learned. These approaches are operant, social learning, and cognitive-behavioral.

In practice, many researchers and practitioners have used procedures that represent combinations of these basic approaches. However, we will use the three groups of interventions to describe the basic procedures and to organize a review of their effectiveness. First, however, it is instructive to review five assumptions proposed by Michelson, Sugai, Wood, and Kazdin (1983, p. 3) that are fundamental to the conceptualization of social skills assessment and intervention plans:

> *Assumption 1:* Social skills primarily are acquired through learning, which involves observation, modeling, rehearsal, and feedback.
>
> *Assumption 2:* Social skills comprise specific and discrete verbal and nonverbal behaviors.
>
> *Assumption 3:* Social skills entail both effective and appropriate initiations and responses.
>
> *Assumption 4:* Social skills are interactive by nature and entail effective and appropriate responses.
>
> *Assumption 5:* Social skills performance is influenced by the characteristics of an environment.

Collectively, these pragmatic assumptions provide direction for both assessment and intervention activities by stressing the multidimensional (verbal–nonverbal and initiating–responding), interactive, situation-specific nature of social skills. Thus, regardless of intervention approach, effective interventions most likely will need to address target behaviors that involve both verbal and nonverbal communications used to initiate or respond to others. With this in mind, we now examine the procedures that are germane to the operant, social learning, and cognitive-behavioral approaches to social skills interventions.

Operant intervention procedures. Operant intervention procedures focus on discrete, observable behavior and the antecedent and consequent events that maintain that behavior. Behavioral control is achieved most often through the use of reinforcement and/or punishment paradigms that are contingent upon a specified behavior. Many social behaviors, however, can be controlled by manipulating preceding events, such as having a peer ask another child to play or a teacher cuing a child to initiate play.

Young children often fail to interact successfully because of a nonresponsive or inhospitable social environment. Here the use of antecedent control can serve to facilitate a positive environment and elicit positive social interactions. With these procedures, a teacher or other intervention agent makes full use of cuing and prompting (Elliott & Gresham, 1991). The key assumption with antecedent control procedures is that a child possesses the necessary social skills but is not performing them at an acceptable rate. Two of the most frequently used antecedent strategies are peer social initiation and cooperative learning.

Peer social initiations have been used by Fenning (1993) and Strain and his colleagues (Strain, 1977; Strain, Shores, & Timm, 1977; Strain & Timm, 1974) to increase the social interaction rates of socially withdrawn preschoolers. This intervention entails training similar-age peer confederates to initiate and maintain social interactions with a withdrawn or isolated child. Overall, this procedure has been effective in increasing positive social behavior in withdrawn preschoolers. It should be noted, however, that when a child's interaction rate approaches zero, peer initiations are likely to be less effective (Elliott & Gresham, 1991). Strain and Fox (1981) provided a detailed review of these procedures for preschoolers and older children.

Another procedure that focuses on manipulating antecedent events is cooperative learning. Cooperative learning provides a prosocial environment in which preschoolers work together to complete specified activities (Doescher & Sugawara, 1989). This procedure requires preschoolers to cooperate, share, and assist each other to complete a task and, as such, represents an effective method for increasing the likelihood of positive social behaviors. When implementing cooperative learning techniques, it is implicitly assumed that children know how to cooperate but are not doing so at optimal levels.

Many operant-learning procedures — that is, the manipulation of antecedents and consequents — have been used to decrease interfering problem behaviors while simultaneously increasing positive social behaviors. These procedures are based on the premise that behaviors are maintained by functional relationships. In other words, reinforcement contingencies (positive or negative) perpetuate low rates of positive social interactions and high rates of negative social interactions. For this reason, it is assumed that a child can perform positive social interaction skills but does not demonstrate the skills due to lack of reinforcement. Given the wealth of studies in this domain, only two of the most frequently used methods will be discussed: contingent social reinforcement and differential reinforcement. Group contingencies (Elliott & Gresham, 1991; McConnell, Sisson, Cort, & Strain, 1991; Litow & Pumroy, 1975) also are used frequently; however, since they have much in common with cooperative learning, they will not be discussed here.

Contingent social reinforcement involves publicly reinforcing a child's socially appropriate behaviors. Allen, Hart, Buell, Harris, and Wolf (1964) demonstrated the efficacy of this method long ago when they applied it to a 4-year-old socially isolated girl. Whenever she interacted with other children, an adult would publicly reinforce her social behavior. This procedure led to a sixfold increase in social interaction rates over baseline levels. Variations of this basic procedure have been successfully extended to children who are electively mute or severely and profoundly mentally retarded (Fenning, 1993; Mayhew, Enyart, & Anderson, 1978). Although this procedure has been found effective, it can require an extraordinary amount of time to ensure that the reinforcement is delivered on a consistent basis. Unless reinforcement is given in a consistent manner, it is doubtful that the intervention will be as effective. This type of contingent social reinforcement is perhaps best used to maintain social interaction rates established through the use of other social skills interventions.

Other operant-learning procedures used to modify social skills are DRO, DRA, and DRL. DRO and DRA are based on the omission rather than the commission of a specific behavior (Cooper, Heron, & Heward, 1987). Therefore, after a certain amount of time, reinforcement is given after any behavior except the target behavior. For example, if one wanted to decrease disruptive behavior while increasing socially appropriate behavior, any behavior exhibited except for disruptive behavior is reinforced after a certain amount of time has elapsed. Hence, this method serves to extinguish undesirable behaviors and increase all other behaviors. Pinkston, Reese, Le Blanc, and Baer (1973) successfully used DRO to decrease a boy's aggressive behavior while at the same time implementing contingent social reinforcement to increase his positive social interaction. In this study, the teacher differentially reinforced positive peer interaction while she ignored aggressive behavior.

Differential reinforcement of low rates of responding (DRL) involves reinforcement to achieve reduction in the frequency of a target behavior. Reinforcers may be delivered either for reduction in overall frequency of a response within a particular time period or for increased elapsed time between responses (interresponse time). For example, if the criterion limit for the DRL was six incidents per hour, the target child would receive reinforcement only if there were six or fewer incidents. Dietz and Repp (1973) successfully used a full-session DRL procedure to decrease the amount of inappropriate talking in an EMR classroom. The DRL contingency was five or fewer "talk outs" per 50-minute class period. This was also applied as a group contingency, because reinforcement was based on the behavior of the entire class.

The aforementioned studies demonstrate that DRO and DRL are effective in decreasing interfering problem behaviors. These procedures probably are most effective, however, when used in conjunction with other social skills interventions, whereby one decreases socially inappropriate behavior while concurrently teaching or reinforcing positive social behaviors.

Social learning intervention procedures. Social learning procedures can be traced back to the social learning theory of Bandura and Walters (1963) and Bandura (1977). From this perspective, social behavior is the result of two types of learning: observational learning and reinforced learning. Social learning theorists differentiate between the learning and the performance of a response. This distinction enables social learning theorists to advocate the process of modeling as a means to acquire new, socially appropriate behaviors. Modeling also affects previously learned responses through its disinhibitory and/or cueing effects. Therefore, children are vicariously reinforced (positively or negatively) by observing a model receive reinforcement for a behavioral performance. In essence, observers tend to inhibit responses that they see punished in others, whereas they are likely to perform modeled behaviors that elicit desired reinforcers.

That modeling promotes social skills in children and youths has substantial empirical support (Gresham, 1985; Wandless & Prinz, 1982). For social skills training, modeling can be divided into two types: (a) live modeling, in which the target child observes the social behaviors of models in naturalistic settings (e.g., the classroom); and (b) symbolic modeling, in which the target child observes the social behaviors of a model via film or videotape. Both types of modeling have been effective in remediating social skills deficits, but most research has focused on symbolic modeling due to the degree of experimental control afforded by videotaped models. Live modeling, however, may be more flexible and efficient in a classroom setting. For instance, Matson, Fee, Coe, and Smith (1991) used peer and puppet models as a novel way to effect a positive change in the social behaviors of preschoolers with developmental disabilities.

A recent development in the realm of social learning has been peer-mediated interventions. These interventions are based on the premise that peers can be effective change agents for children with social skills performance deficits. Empirically, it has been shown that peers can serve to differentially reinforce appropriate social interactions and influence the occurrence of positive social behaviors (Mathur & Rutherford, 1991). Peer-mediated interventions may be more successful than teacher-mediated interventions because peer confederates may be better able to consistently monitor and differentially reinforce their peers. Additionally, peer mediation can be cost-effective because it minimizes teacher involvement.

Cognitive-behavioral intervention procedures. Cognitive-behavioral intervention procedures are a loosely bound group of procedures that focus on children's internal regulation of their behavior. In particular, cognitive-behavioral approaches to social skills training emphasize a child's ability to problem solve and to self-regulate behavior. For preschoolers, two of the most frequently used cognitive-behavioral social skills procedures are coaching and problem solving.

Coaching, unlike modeling, is a direct verbal instruction technique that involves a coach (usually a teacher or a psychologist, occasionally a peer) who has knowledge about how to enact a desired behavior. Most coaching procedures involve three basic steps: (a) a student is presented with rules for or the standards of a specific behavior; (b) a selected social skill is rehearsed with the coach; and (c) the coach provides specific informational feedback during behavioral rehearsal and gives suggestions for future performances. In some instances, modeling may be included in the coaching procedure to give the child a better understanding of the topography of the social behavior and, if praise is given, reinforcement may occur. Therefore coaching, although conceptualized as a procedure that requires the child's cognitive skills to translate instruction into desired behaviors, can be enhanced with behavioral and/or social-learning procedures.

Coaching has received considerable empirical support as a social skills training procedure. For example, Oden and Asher (1977) used coaching to effectively teach participation, communication, cooperation, and peer reinforcement. In addition, sociometric ratings of coached students increased when compared to noncoached students. Ladd (1981) obtained similar results when using a coaching procedure to those of Gottman, Gonso, and Schuler (1976).

Several interventions have been developed that stress teaching children the process of solving social or interpersonal problems as a way to facilitate socially appropriate behaviors. As Weissburg (1985) pointed out, some of these intervention programs, which are largely classroom-based, have been called social problem-solving (SPS) programs, whereas others have been called interpersonal cognitive problem-solving (ICPS) programs. ICPS programs generally place greater emphasis on cognitions that parallel social problem situations and employ narrower training procedures than SPS approaches; however, both use a similar training sequence to help students identify and cope with social problems. Briefly, the steps can be described as (a) identify and define the problem, (b) determine alternate ways of reacting to the problem, (c) predict consequences for each alternative reaction, and (d) select the best or most adaptive alternative. Social problem-solving methods can be used with individual children or with entire classrooms. It should be noted, however, that these methods often are cognitively too complex for most preschoolers and do not focus on discrete social skills training; learning social skills generally requires more skill-oriented, externally reinforcing procedures than are offered by a strictly cognitive approach.

Effectiveness of Interventions and Suggestions for Practice

The popularity and widespread use of social skills training procedures have resulted in several major reviews of the effectiveness of these procedures with children (see Cartledge & Milburn, 1986; Elliott & Gresham, 1993; Gresham, 1981, 1985; Ladd & Mize, 1983; Schneider & Byrne, 1985). With regard to child characteristics, Schneider and Byrne, who conducted a large meta-analysis of social skills training studies, indicate that social skills interventions are more effective for preschoolers and adolescents than elementary children. No gender differences in effect sizes are noted, although few studies have treated gender as an independent variable. In addition, social skills training was found to be more effective for students exhibiting social withdrawal or learning disabilities than for aggressive students.

Based on the reviews of research by Elliott and Gresham (1993), Schneider and Byrne (1985), and Mastropieri and Scruggs (1985–86), there appears to be substantial support for the effectiveness of social skills training procedures in general, and in particular for operant and modeling procedures. Practical suggestions from the research literature for individuals interested in facilitating the development of social skills in young children include the extensive use of operant methods to reinforce existing social skills. These basic operant tactics include (a) the manipulation of environmental conditions to create opportunities for social interactions that prompt or cue socially desired behavior in a target child, and (b) the manipulation of consequences so that socially appropriate behavior is reinforced and socially inappropriate behavior, whenever possible, is ignored rather than punished. In addition, modeling of appropriate social behavior supplemented with coaching, feedback, and reinforcement should be a primary tactic in developing new social behaviors in children.

Facilitating Generalization of Social Skills

Social skills training often results in positive outcomes; however, treatment effects often are short-lived and fail to generalize (Berler, Gross, & Dabman, 1982). For treatments delivered in social skills training to be considered truly effective and valid, levels of change must evidence treatment generality. Treatment generality is comprised of maintenance (behavior change that persists over time) and generalization (behavior changes that occur under nontraining conditions) (Cooper et al., 1987). Although treatment generality often is evaluated as a hope-for-the-best side effect of social skills training, maintenance and generalization should be systemic facets of any training program. Several authors have discussed procedures to enhance treatment generality (e.g., Michelson et al., 1983; Stokes & Baer, 1977; Stokes & Osnes,

FIGURE 2. A social skills intervention progress-monitoring record sheet.

A Social Skills Intervention Progress-Monitoring Record

Student's Name ______________________ Teacher/Grade ______________

Group Leader ______________________ Date Program Began ______________

Skill Domains, Subdomains, and Behavioral Objectives	Progress Assessment				
Cooperation	Check Skills to be taught	No Progress	Improvement Observed	Mastered in Treatment Group	Generalized
1. Ignoring disractions					
2. Making transitions					
3. Using free time					
Classroom Interaction Skills					
1. Finishing assignments on time					
2. Keeping desk clean, putting away materials					
3. Producing correct work					
4. Paying attention and following directions					
5. Using time appropriately when waiting					
Assertion					
Conversation Skills					
1. Giving a compliment					
2. Introducing oneself					
3. Making positive self-statements					
4. Initiating conversation					
5. Telling an adult about unfair treatment					
Joining and Volunteering Skills					
1. Joining ongoing activities					
2. Volunteering to help peers					
3. Inviting others to join activities					
Responsibility					
1. Asking an adult for help					
2. Paying attention to a speaker					
3. Refusing unreasonable requests					
4. Answering the telephone					
5. Introducing oneself to new people					
6. Asking permission to use property					
7. Asking permission to leave house/property					
8. Reporting accidents to appropriate persons					
9. Questioning rules that may be unfair					
10. Responding to a compliment					

1989). These generality facilitators include (a) targeting behaviors that will be maintained by natural reinforcement contingencies; (b) training across different behaviors, settings, and persons; (c) training loosely, i.e., varying stimuli such as reinforcers, and tone of voice; (d) systematically withdrawing or fading intervention procedures to approximate the natural environment; (e) reinforcing behavior change in novel and appropriate settings; (f) including peers in training; and (g) providing booster sessions. Programming for generality should occur for both child and treatment agent (e.g., parent or teacher) behaviors. Incorporating as many generality facilitators as possible into social skills interventions should enhance the likelihood of treatment maintenance and generalization.

Evaluation of Intervention Effectiveness

The final leg of the social skills training journey invariably rests with the deceptively simple question, "Was the intervention effective?" Although many practitioners and researchers assess treatment effectiveness as a matter of course, methodologically sound measurement often is overlooked in evaluations of intervention effectiveness. Treatment evaluation extends beyond simply assessing changes in social skills at the completion of treatment. Evaluation should include ongoing assessments of acceptability, integrity, social validity, and generality. Ideally, assessments of intervention effectiveness will be multifaceted, involving multiple settings, informants, and methods.

Important advances in the monitoring and the evaluation of interventions have occurred recently. These advances include the use of goal attainment scaling, progress-monitoring records (Figure 2), reliability change indexing (Gresham, 1993), and the integration of visual and statistical analyses (Busse, Kratochwill, & Elliott, in press). The progress-monitoring record illustrated in Figure 2 often has been used as part of a goal-setting and self-monitoring process with elementary and middle school students; however, no reports of its use with preschoolers have been published.

SUMMARY: AN IMPLEMENTATION FRAMEWORK FOR SOCIAL SKILLS ASSESSMENT AND INTERVENTION

A general framework for social skills training can be described by the acronym DATE. First, behaviors are *defined* and stated in observable terms, as are also the conditions (antecedent and consequent) surrounding the behavior. Second, behaviors are *assessed*, preferably via multiple methods that include rating scales, direct observations of the child, interviews with teachers and/or parents, and occasionally a structured role-play to confirm deficits and to refine intervention plans. Third, *teaching* strategies are prescribed to fit the student's needs as determined by assessment results and the classification that best characterizes the child's social skills deficits. Fourth, the effects of the teaching procedures are *evaluated* empirically by using the assessment methods through which students were selected for training. This Define-Assess-Teach-Evaluate (DATE) model is applied continuously to each deficient social behavior the student exhibits.

The DATE model can be implemented by a teacher, psychologist, or other specialist through five steps: (a) establishing the need for performing the behavior, (b) identifying the specific behavioral components of the skill or task analysis, (c) modeling the behavior, (d) obtaining behavior rehearsal and response feedback, and (e) generalizing training. These five steps represent an easily implemented and generic approach to teaching positive social behavior by using the intervention procedures that consistently have been found to be most effective with young children.

Best Practices in Social Skills Training

Frank M. Gresham
University of California–Riverside

OVERVIEW

The assessment and facilitation of social competence continues to be an important area of concern for school psychologists. Schools are one of the most important settings in which children acquire, develop, and refine the skills that are essential for establishing and maintaining interpersonal relationships. Successful and mutually beneficial interactions with peers and significant adults represent an important developmental accomplishment that is predictive of long-term life adjustment (Asher, 1990; Coie, 1990; Parker & Asher, 1987; Schneider, 1993).

Social skills are the tools with which positive and rewarding relationships are built and negative and pernicious relationships are modified or eliminated. Some children, however, lack the necessary tools to build, maintain, or terminate interpersonal relationships. Deficiencies in social competence have been related to poor academic performance, social maladjustment, peer rejection, and psychopathology (Kupersmidt, Coie, & Dodge, 1990; Parker & Asher, 1987). Relatively large mean differences in social competence have been found between nondisabled children and children with learning disabilities (Gresham, 1992; LaGreca & Stone, 1990; Swanson & Malone, 1992), mental retardation (Gresham & Reschly, 1987, 1988; Morrison, Forness, & MacMillan, 1983), behavior disorders (Coie & Koeppel, 1990; Stumme, Gresham, & Scott, 1982; Walker & McConnell, 1988), and attention deficit hyperactivity disorders (Landau & Moore, 1991). This literature suggests that children with mild cognition and behavioral disabilities experience substantial difficulties in social competence.

Schools as Settings for Social Skills Interventions

As a microcosm of society, the school is a place where children and adults work, play, eat, and live together for 6 hours per day, 5 days per week, and at least 180 days per year. At a minimum, children spend approximately 5,400 hours per year in school and are exposed to numerous social interactions. Schools, as social settings, represent environments that are ideal for teaching social behavior.

Social skills interventions in schools take place both informally and formally. Informal social skills instruction is based on the principle of incidental learning, which takes advantage of naturally occurring behavioral events or incidents to teach appropriate social behavior. Most social skills instruction in schools can be characterized as informal and incidental. Literally thousands of behavioral incidents occur in a classroom over the course of an academic year and these incidents can be used as the basis for social skills instruction. For this reason, informal and incidentally taught social skills have greater potential for generalization than social skills taught in more formal and less naturalistic settings.

Formal social instruction can take place in a classroom setting in which the entire class is exposed to a social skills "curriculum" or in a small group setting removed from the classroom. This chapter focuses upon incidental teaching of social skills and social skills instruction in small-group settings. For more detailed information regarding classwide social skills instruction readers should consult other comprehensive treatments of this literature (Elias & Clabby, 1992; Elias & Branden, 1988; Weissberg, Caplan, & Harwood, 1991).

Defining Social Competence

Part of the difficulty in defining social competence has been the failure by many to distinguish between social skills and social competence. McFall (1982) argued that *social skills* are behaviors exhibited in specific situations that result in judgments of *social competence*. Social skills are behaviors that lead others to judge whether a behavioral performance was competent. Therefore, social skills are behaviors and social competence represents "judgments" about those behaviors. These judgments may be based on opinions of significant others (e.g., teacher, parents, peers), comparisons with explicit

BEST COPY AVAILABLE

criteria (e.g., number of social tasks performed correctly in relation to some criterion), or comparisons with an appropriate normative sample.

Gresham (1983) developed a *social validity* definition of social skills, in which social skills are defined as socially significant behaviors, exhibited in specific situations, that predict important social outcomes for children and youth. *Socially significant* behaviors are behaviors that treatment consumers consider important and desirable and that predict an individual's standing on socially important outcomes. *Socially important* outcomes are outcomes that treatment consumers judge to be important, adaptive, and functional. In most settings relevant for children and youths, important social outcomes include, but are not limited to, (a) peer acceptance, (b) friendships, (c) significant others' judgments of social skill, (d) positive feelings of self-worth, (e) academic achievement, and (f) positive adaptation to school, home, and community environments, as judged by significant others who regulate these environments.

The social validity concept of social skills has the advantage of specifying behaviors in which a child may be deficient, but it also can define these behaviors as socially skilled on the basis of their relationship to socially important outcomes. This social validity definition of social skills is broader than McFall's (1982) social competence definition, because it expands the concept of "judgment" to include additional criteria in defining social competence (e.g., peer acceptance, friendships, achievement, school adaptation, etc.). Social validity constitutes an important type of validity in interventions with children and youths and has been an important standard against which the success of behavioral interventions has been judged (Kazdin, 1977; Wolf, 1978).

Classification of Social Skills Deficits

An important distinction to be made in the assessment of social skills is the differentiation between *acquisition* and *performance* deficits (Gresham, 1981a, 1981b). This distinction is important because it suggests different intervention approaches in remediating social skills deficits. The notion of social skills *acquisition deficits* refers to the absence of particular social skills from a behavioral repertoire. Social skills acquisition deficits reflect the absence of knowledge for executing given social skills even under the optimal conditions. *Social performance deficits* represent the presence of social skills in a behavioral repertoire but the failure to perform these skills at acceptable levels in given situations.

Gresham and Elliott (1990) extended this two-way classification into a four-category classification scheme. Most children exhibit some social behaviors in each of these four categories. This scheme incorporates two dimensions of behavior: (a) social skills and (b) interfering problem behaviors. Children may have acquisition or performance deficits with or without problem behaviors. Interfering problem behaviors include internalizing (e.g., anxiety, depression, etc.) and externalizing (e.g., aggression, impulsivity, etc.) that prevent the acquisition or performance of socially skilled behavior. Figure 1 shows this four-category classification scheme.

The classification scheme shown in Figure 1 is pivotal in linking assessment results to interventions for social skills deficits. It does not make much sense to teach a social skill to children who already have the skill in their repertoires. This would be analogous to teaching single-digit addition to calculus students in high school. Many, if not most, children have social performance deficits. This being the case, the goal of the intervention should be to increase the frequency with which the behavior is exhibited in specific situations rather than teach the skill. Fewer students have acquisition deficits; thus intervention must emphasize promoting skills acquisition. These differential intervention strategies for acquisition and performance deficits are discussed in greater detail later in this chapter.

BASIC CONSIDERATIONS

An in-depth discussion of social skills assessment methods is beyond the scope of the present chapter. There are, however, several key factor that should be recognized in linking social skills assessment and intervention strategies. Table 1 presents 12 major goals of social skills assessment. These goals include the five major stages of the assessment/intervention sequence: (a) screening/selection, (b) classification, (c) target behavior selection, (d) functional analysis, and (e) evaluation of intervention.

Although a number of social skills assessment methods have been developed, three methods are the most commonly used: ratings by other, peer-referenced assessment, and naturalistic observations. These methods are discussed in greater detail in other sources (Gresham, 1986; Gresham & Little, 1993; LaGreca & Stark, 1986; McConnell & Odom, 1986).

Social skills training rests on the fundamental assumption that children learn social skills through the processes of observational, instrumental (operant), and respondent (classical) learning (Elliott & Gresham, 1991). There are numerous variables that may account for deficits in prosocial behavior; however, many of these variables either are highly inferential (e.g., repressed hostile feelings, poor ego controls, etc.) or are beyond anyone's control (e.g., developmental immaturity, inadequate cognitive abilities, etc.). Elliott and Gresham (1991, 1993) described a model of variables that influence social skills deficits and that can be used to remediate social skill deficiencies. This model suggests that social skills deficits may result from five factors: (a) lack of cues

FIGURE 1. Classificaton of social skills deficits.

or opportunities to learn or perform prosocial behaviors; (b) presence of interfering problem behaviors that block acquisition or impede performance of prosocial behaviors; (c) lack of knowledge; (d) lack of sufficient practice or feedback for prosocial behavioral performances; and (e) lack of reinforcement for performance of prosocial behaviors.

Social Skills Training Variables

Four fundamental processes underlie all social skills training techniques discussed in this chapter. These training variables are instruction, rehearsal, feedback/reinforcement, and reductive procedures; they are based, in part, on the theoretical work of Ladd and Mize (1983). Each of these variables is discussed briefly in the following sections.

Instruction. There are two types of instructions: verbal and modeled. Verbal instruction typically involves the use of spoken language to describe, prompt, explain, define, and/or request social behavior. Verbal instruction may involve the use of concrete or abstract concepts to facilitate the acquisition of social skills. The training procedures of coaching and direct instruction rely primarily on verbal instruction.

Modeled instruction involves the use of live or filmed performance or enactments of behaviors that illustrate social skills. The major advantage of modeled instruction is that children learn how to combine, chain, and sequence behaviors that make up particular social skills. The adage "a picture is worth a thousand words" captures the essence of modeled instruction.

Rehearsal. Rehearsal is the repeated practice of a social skill that promotes the retention of the skill concept and leads to more polished and effective behavioral performances. Rehearsal can be overt, covert, or verbal. *Overt rehearsal*, typically called behavioral rehearsal, is the repeated practice of the observable behaviors involved in the performance of a social skill. *Covert rehearsal* refers to thinking about or imagining behavioral performances of a social skill. Covert rehearsal of instructed social skills allows for retention of instructed information as well as more effective behavioral performances of the social skill (Elliott & Gresham, 1993).

Verbal rehearsal entails the verbal report or recitation of the components of a particular social skill. The learner says what he or she might do in a particular social situation, whereas overt rehearsal requires the learner to actually enact or perform the social skill and covert rehearsal requires the learner to think about or imagine rather than say or perform a social skill.

Feedback and reinforcement. Feedback is the information that is provided a learner regarding the correspondence between a social skill performance and some standard of performance. Feedback can take two forms: evaluative and informative. *Evaluative feedback* informs the learner of the extent to which a given behavioral performance matched an external criterion or standard. *Informative feedback* gives the learner specific information regarding the reasons for effective and ineffective performances of a given social skill. Informative feedback is the preferred type of feedback to be used in social skills training, because it allows for modification of behavioral performances.

Reinforcement involves the presentation or removal of environmental events that increase the frequency of behavior. Reinforcement can be positive or negative. With positive reinforcement, an environmental event is presented that increases the frequency of a behavior. Positive reinforcement is perhaps the most frequently used social skills training strategy (Barton, 1986).

With negative reinforcement, an environmental event that increases the frequency of behavior is *removed*. Negative reinforcement always involves either escape or avoidance learning. That is, a person's behavior will be negatively reinforced if that behavior allows the person to escape or avoid an aversive stimulus. Escape learning results in termination of an ongoing aversive stimulus, whereas avoidance learning prevents the presentation of the aversive stimulus. For instance, some children in classrooms exhibit disruptive behavior to escape or avoid academic assignments that they consider aversive. Negative rein-

forcement is not used as frequently as positive reinforcement in social skills training.

Reductive processes. Social skills training focuses on teaching prosocial behaviors to children. The presence of interfering problem behaviors, however, often prevents the acquisition or hinders the performance of social skills. Reductive procedures present or remove environmental events in order to *decrease* the frequency of problem behaviors. These procedures, to be discussed later, include response cost, overcorrection, and differential reinforcement techniques.

BEST PRACTICES IN SOCIAL SKILLS TRAINING

As an intervention process, social skills training has four objectives: (a) promoting skills acquisition, (b) enhancing skills performance, (c) removing interfering problem behaviors, and (d) facilitating generalization of prosocial behavior. These objectives reflect the type of social skills deficiency (i.e., acquisition versus performance deficit), the presence or absence of interfering problem behaviors, and the functional control of social behaviors in specific situations. Figure 2 lists specific social skills intervention strategies that are appropriate to each training objective. Specific step-by-step intervention procedures and recommendations can be found in the *Social Skills Intervention Guide* (Elliott & Gresham, 1993).

In social skills training it must be recognized that a given child may have some acquisition deficits, some performance deficits, and some interfering problem behaviors. Professionals in charge of social skills interventions must match appropriate intervention strategies with the particular deficits or behavioral excesses the child exhibits. Moreover, a common misconception is that one seeks to facilitate generalization after presenting procedures for acquisition or performance as part of a final stage of intervention. The evidence is clear that best practice is to incorporate generalization from the very beginning of any social skills training program (Elliott & Gresham, 1991, 1993).

Promoting Skills Acquisition

Procedures designed to promote acquisition are applicable when children do not have a particular social skill in their repertoire, when they do not know a particular step in the performance of a behavioral sequence, or when their execution of the skill is awkward or ineffective. It should be noted that a relatively small percentage of children will need social skills interventions based on acquisition deficits: Far more children have performance deficits in the area of prosocial behavior (Gresham, 1981a; Gresham & Reschly, 1988).

Three procedures represent pathways to remediation of deficits in social skill acquisition: modeling, coaching, and behavioral rehearsal. Social problem solving is another pathway, but it is not discussed here owing to space limitations and the fact that it incorporates the three procedures discussed in this section. More specific information on social problem-solving interventions can be found in Elias and Clabby (1992) and Elias and Branden (1988).

Modeling is the process of learning a behavior by observing another person performing that behavior. Modeling instruction presents the entire sequence of behaviors involved in a particular social skill and teaches how to integrate specific behaviors in this sequence into a composite behavioral pattern. Modeling is one of the most effective and efficient ways of teaching social behavior (Gresham, 1985; Schneider, 1993).

Coaching is the use of verbal instruction to teach social skills. Unlike modeling, which emphasizes visual displays of social skills, coaching emphasizes a child's cognitive and language skills. Coaching is accomplished in three fundamental steps; (a) present-

FIGURE 2. Social skills interventions by type of social skills deficit.

ing social concepts or rules, (b) providing opportunities for practice or rehearsal of a social skill, and (c) providing specific informational feedback on a behavioral performance.

With coaching, one can transmit general principles of social interaction, integrate behavioral sequences in performing a social skill, set social goals of an interaction sequence, and help children become aware of their social impact on others (Renshaw & Asher, 1983). It is assumed that children can use general principles of social interaction to guide their behavior in specific social situations. In this sense, coaching is based, in part, on the notion of "rule-governed" rather than "contingency-shaped" behavior. In rule-governed behavior, not every situation a child is likely to encounter has to be taught. Instead, the goal is to teach social rules that a child can apply in a variety of situations. Theoretically, this should lead to greater generalization of social skills.

Behavioral rehearsal refers to practicing a newly learned behavior in the structured, protective situation of role playing. In this way, children can enhance their proficiency in using social skills without experiencing adverse consequences. Social learning theory suggests that behavioral rehearsal is essential to learning social behavior (Bandura, 1977).

Three forms of behavioral rehearsal can be used in a number of ways and combinations. For example, one can ask children to imagine being teased by another child and then to imagine how they would respond (covert rehearsal). Next, one might combine covert rehearsal with verbal rehearsal by asking students to recite the specific behaviors they would exhibit in imagined situations. Finally, one might combine covert and verbal with overt rehearsal by asking students to role play the imagined situation.

Enhancing Performance of Social Skills

Most social skills interventions will involve procedures that increase the frequency of prosocial behaviors, because most social skills deficits, as has been noted, are performance (won't do) rather than acquisition (can't do) deficits. This suggests that most social skills interventions for most children will take place in naturalistic environments (e.g., classrooms, playgrounds, etc.) rather than in small "pullout" groups. Therefore, most social skills interventions can be facilitated by using a consultative framework for intervention. Failure to perform certain social skills in specific situations result from two fundamental factors: (a) inappropriately arranged antecedents and/or (b) inappropriately arranged consequences. A number of specific procedures can be classified under the broad rubrics of antecedent and consequent strategies.

Antecedent strategies. Interventions based on antecedent control assume that the environment does not set the occasion for the performance of prosocial behavior. That is, cues, prompts, or other stimuli are either not present or the child does not discriminate these stimuli in relation to the performance of prosocial behavior. Antecedent control techniques are based on the principle of discrimination learning. Briefly, a discrimination is made when a behavior is reinforced in the presence of one stimulus, but not in the presence of another stimulus. If these stimuli are not present or if the learner does not discriminate them, the behavior will not be performed. Intervention procedures based on the control of antecedents focus on presenting and/or enhancing stimuli that set the occasion for prosocial behavior.

Two general strategies fall under the category of antecedent strategies: peer-mediated interventions and cuing/prompting. Peer-mediated interventions can include three techniques: (a) peer initiations, (b) peer tutoring, and (c) peer modeling (Kohler & Strain, 1990). With peer initiation strategies, a child's peers are used to initiate and maintain social interactions with socially isolated or withdrawn students. These strategies are effective for students who exhibit performance deficits and who evidence relatively low rates of social interaction.

In using peer initiation, peer confederates are recruited and instructed in the specific behaviors that are required to initiate and maintain a social interaction. Specific feedback is given to peer confederates that is based on role-played examples of peer initiations. Finally, peer confederates are instructed to initiate interactions with targeted children and to report any problems they encounter in their initiation efforts. Peer initiation strategies are effective in increasing the social functioning of socially withdrawn children in naturalistic settings.

Peer tutoring traditionally has been used to teach academic skills. Although there are no controlled studies in the literature, peer tutoring is a potentially effective strategy for teaching social behavior. In many cases peers may be more realistic and convincing teachers of social skills than adults because of their familiarity with peer group mores, values, and customs. Peer tutoring is closely related to coaching as an intervention strategy that relies on verbal instruction, role playing, and verbal feedback (Oden & Asher, 1977).

Since peers serve as models for social behavior in peer modeling, the techniques can be considered an antecedent control strategy because a peer provides discriminative stimuli for the performance of social behavior. Peer modeling has been used extensively in social skills interventions (Strain & Fox, 1981).

A cuing and prompting procedure uses verbal or nonverbal cues or prompts to facilitate prosocial behaviors. Simple prompts or cues for some children may be all that is needed to signal to children to engage in socially appropriate behaviors. Cuing and prompting represent one of the easiest and most efficient social skills intervention strategies.

Consequent strategies. Intervention techniques that rely on consequent control techniques can be classified into three categories: (a) reinforcement-based strategies, (b) behavioral contracts, and (c) school–home notes. Reinforcement-based strategies assume that a child knows how to perform a social skill but is not doing so because of little or nonexistent reinforcement for the behavior. Reinforcement strategies include attention, tokens, points, and activity reinforcers, as well as group-oriented contingency systems; more comprehensive discussion of these procedures can be found in Martens and Meller (1990).

Behavioral contracts are written agreements between students and intervention personnel that specify the relation between behavior and its consequences. Behavioral contracts should have the following five components: (a) specification of mutual gains, (b) ways in which the child will demonstrate observable behavior, (c) provisions for sanctions for not meeting contract terms, (d) a bonus clause for consistent performance of desired behaviors, and (e) means of monitoring reinforcers given and received (Stuart, 1971). Behavioral contracts are an effective means of enhancing the performance or quality of prosocial behavior.

School–home notes are written communications sent by intervention personnel to parents on a daily or weekly basis. School–home notes can be easily incorporated into behavioral contracts to enlist parental involvement and cooperation in facilitating prosocial behavior. More extensive discussion of using school–home notes can be found in Kelley and Carper (1988).

Removing Interfering Problem Behaviors

Students may not acquire or may not perform certain social skills because problem behaviors interfere with or block their acquisition or performance. The social skills classification model presented earlier distinguishes between acquisition and performance deficits that are associated with interfering problem behaviors.

Three general strategies may be used to remove or reduce interfering problem behaviors: (a) differential reinforcement, (b) positive practice, and (c) response cost. In differential reinforcement, a particular behavior is reinforced in the presence of one stimulus and is not reinforced in the presence of another stimulus. In other words, the purpose of differential reinforcement is to get a behavior under stimulus control.

One differential reinforcement technique known as differential reinforcement of other behavior (DRO) refers to the delivery of a reinforcer after any appropriate behavior except the target behavior selected for reduction. The effect of DRO is to reduce a target behavior and increase other behaviors. Another differential reinforcement technique, known as differential reinforcement of low rates of behavior (DRL), a specific number of reductions in a target behavior in a specified time interval is reinforced. For example, reductions in a target behavior by 50% in a class period may be reinforced, thereby reducing the overall rate of the inappropriate target behavior. Finally, in differential reinforcement of incompatible behaviors of DRI, behaviors that are incompatible with the target behavior are reinforced. For instance, talking nicely to others is incompatible with yelling at others. Thus, if talking nicely is reinforced more frequently than yelling, talking will increase and yelling will decrease.

Positive practice is a component of overcorrection that reduces the frequency of problem behavior. It is the repeated practice of an appropriate behavior that is incompatible with an inappropriate behavior. If a student, for example, insulted another student (e.g., "You're really ugly"), he or she would have to practice saying nice things or giving compliments to the insulted child, to each person in the class, and perhaps even the teacher. Positive practice should be part of every social skills intervention program because intervention personnel can use naturally occurring behavioral incidents to teach the prosocial alternative to inappropriate behavior.

Response cost is the removal of a specified amount of a positive reinforcer to decrease the frequency of a target behavior. In practice, response cost usually takes the form of fines or penalties for inappropriate behavior. Response cost can be used in conjunction with group contingency systems, school–home notes, and behavioral contracts. Response cost is more user-friendly than the labor-intensive reductive procedures of DRO, DRL, and DRI. A more detailed discussion of reductive procedures can be found in Lentz (1988).

Facilitating Generalization

Social skills would not be particularly functional if they did not occur outside the setting in which they were taught. The ultimate goal of social skills interventions is to have trained behaviors occur in diverse settings and situations, and to be maintained over time. Thus, three types of generalization are relevant for social skills interventions: (a) setting generalization, (b) behavior generalization, and (c) time generalization.

Setting generalization is the occurrence of a behavior in settings or situations other than those in which the social skill was taught. One reason behavior generalizes across settings or situations is that settings and situations often have common properties. The more closely the generalization setting resembles the training setting, the greater the degree of setting generalization.

Behavior generalization is changes in behavior that are not the direct focus of social skills training. For example, changes in sharing behavior may also produce changes in complimenting others even although complimenting was not a target behavior. If behaviors are members of the same functional response class, then behavior generalization can be facilitated by teaching only a subset of that response class.

Time generalization, or maintenance, is the continuation or maintenance of behavior after an intervention has been withdrawn. Several factors account for time generalization. Some social behaviors taught in social skills training have a high probability of being reinforced in the future. Some behaviors taught in social skills training produce their own reinforcing consequences. Finally, some behaviors may produce permanent changes in the behavior of significant others such as parents or teachers.

Stokes and Osnes (1989) presented a comprehensive discussion of 12 generalization programming strategies. These strategies are classified under three broad categories of generalization programming: (a) exploiting functional contingencies, (b) training diversely, and (c) incorporating functional mediators. A detailed discussion of these strategies is not possible, given the space constraints; however, several techniques can be highlighted.

Two strategies under the category of training diversely are useful generalization programming techniques: training sufficient stimulus exemplars and training sufficient response exemplars. Diverse stimulus exemplars incorporate varied stimulus conditions in teaching a social skill. This represents training for stimulus generalization. In training for response generalization, one provides sufficient response exemplars by teaching children as many ways as possible to respond in the same social setting or situation — in other words, by giving students sufficient "behavioral ammunition."

Teaching behavior that is relevant to a given environment is another way to promote generalization. To get a behavior to enter an environment that reinforces the behavior without any special programming, relevant behaviors should be taught. The relevance of a particular social skill depends on the behavioral standards, expectations, and requirements of particular social environments. In order to teach relevant behaviors for given environments, it is necessary to know what is relevant in those environments.

The behaviors taught to a child in social skills training should have social validity. That is, the behaviors should be socially significant behaviors as judged by significant others in the child's environment. By teaching behaviors that are considered by others to be socially significant, one increases the chances that these behaviors will enter a natural community of reinforcement. More detailed discussions of generalization can be found in other sources (Edelstein, 1989; Fox & McEvoy, 1993; Stokes & Osnes, 1989).

SUMMARY

Social skills are behavior that lead to judgment of social competence by others; they are the tolls by which children and youths build, maintain, and improve the quality of their interpersonal relationships. Social skills were defined in this chapter as socially significant behaviors, exhibited in specific situations, that predict important social outcomes for children and youths. Social skills deficits were classified as being either acquisition deficits or performance deficits, which may or may not be accompanied by interfering problem behaviors. This classification was seen as essential in determining the most appropriate social skills intervention strategy.

Four processes underlying all social skills training techniques were discussed: instruction, rehearsal, feedback/reinforcement, and reductive processes. These processes form the basis for social skills training strategies of modeling, coaching, behavioral rehearsal, reinforcement, and punishment. Social skills training was viewed as having four fundamental objectives: (a) promoting skill acquisition, (b) enhancing skill performance, (c) removing interfering problem behaviors, and (d) facilitating generalization of prosocial behavior. Specific strategies for accomplishing each of these four objectives were defined and discussed.

ANNOTATED BIBLIOGRAPHY

Asher, S. R., & Coie, J. D. (Eds.). (1993). *Peer rejection in childhood.* New York: Cambridge University Press.
This edited volume presents and integrates knowledge about children's peer relationships with a particular focus on peer rejection. The book is composed of 13 chapters, written by leading developmental researchers in the area of peer relationships, that are organized under five headings: (a) behavioral characteristics of peer-rejected children (three chapters), (b) social-cognitive processes (two chapters), (c) parent–child relations and peer rejection (two chapters), (d) consequences of peer rejection (two chapters), and (e) issues in intervention research (two chapters). The book ends with a chapter detailing a developmental theory of peer rejection.

Elliott, S. N., & Gresham, F. M. (1992). *Social skills intervention guide.* Circle Pines, MN: American Guidance Service.
The *Social Skills Intervention Guide* (SSIG) is a systematic approach to teaching social skills to children between the ages of 6 and 16 years. A system for classifying social skills deficits based on acquisition/performance deficits and presence/absence of interfering problem behaviors is described. Implementation issues such as selection and grouping of students, establishing group rules, and a means of monitoring students' progress are described. Social skills training techniques based on instruction, rehearsal, reinforcement, and reductive processes are discussed in relation to accomplishing the objectives of promoting skill acquisition, enhancing skill performance, removing interfering problem behaviors, and facilitating generalization of prosocial behaviors.

Gresham, F. M., & Elliott, S. N. (1990). *Social Skills Rating System.* Circle Pines, MN: American Guidance Service.
The *Social Skills Rating System* (SSRS) is a broad, multirater assessment of student social behaviors that can affect teacher–student relations, peer acceptance, and academic performance. The SSRS is a nationally standardized, norm-referenced series of teacher, parent, and self-report rating scales for children and adolescents between the ages of 3 and 18 years. Norms are stratified into three developmental levels: preschool (ages 3–5 years), elementary (ages 5–12 years), and secondary (ages 13–18 years). The SSRS measures social skills in the domains of cooperation, assertion, responsibility, empathy, and self- control and interfering problem behaviors in the areas of externalizing, internalizing, and hyperactivity problems. The teacher scale also includes a rating measure of academic performance.

Hansen, D. J. (Ed.). (1993). Social-skills assessment and intervention with children and adolescents. [Special issue]. *Behavior Modification, 17*(3), 227–366.
This special issue discusses the evolving data base and best practices in social skills assessment and intervention. Five articles written by leading researchers in the field of social skills assessment and training are included; they address the following topics: (a) developmental issues in social skills assessment and intervention (b) assessing acceptance and social skills with peers, (c) social skills interventions with children, (d) social skills interventions with adolescents, and (e) assessing and enhancing generalization and social validity of social skills interventions.

Walker, H. M., Todis, B., Holmes, D., & Horton, G. (1988). *The Walker Social Skills Curriculum: The ACCESS Program.* Austin, TX: PRO-ED.

This curriculum is designed for adolescents with mild handicaps and is based on principles of direct instruction. The ACCESS program teaches 31 social skills distributed across three broad social skills domains: (a) peer-related social skills, (b) adult-related social skills, and (c) self-related social skills. The curriculum is designed for small-group (five or fewer) instruction and uses scripted lessons.

Best Practices in Working with Students with Autism

Lorna Volmer
Heartland AEA, Iowa

OVERVIEW

Students with autism have a diagnosis that is associated with a medical model (Reschly, 1992), although the diagnosis may be made by professionals in a variety of settings. Although the diagnosis is medical, problem solving provides a useful approach to the difficulties faced by these students. The problem-solving approach currently is being embraced over the classification system because diagnostic categorization has not enhanced treatment (Reschly, 1992). However, in working with students with autism, the problem-solving approach and a diagnosis complement each other: The diagnosis of autism creates an understanding of the unique characteristics of the student as well as interventions that can be used most effectively. The diagnosis also can be vitally important to families as they seek support and begin to understand the long-term implications.

For students with autism, the diagnosis is a critical step in developing appropriate educational interventions. These students perceive the world differently from the majority of the population. To teach them effectively, educators must acknowledge those differences and set up an environment that enables them to learn. Although the typical environment in the schools is not necessarily well suited for students with autism, it can be adapted to suit their needs. The diagnosis of autism does not predict an educational program. Interventions or programs should always consider the needs of the student; however, the diagnosis does suggest several strategies that have been successful with autistic students (Landrus & Mesibov, 1986; Szatmari, 1991).

The diagnosis can be important to educators and to families. The family of a student with autism shares with the families of other developmentally disabled individuals many frustrations and stresses. Yet families with an autistic child typically have borne a greater degree of misunderstanding and blame than other families (Cutler & Kozloff, 1987). These families have to deal on a daily basis with a child who may not be able to communicate wants and needs, has bizarre and ritualistic behaviors, and may not recognize dangers. They are forced to adopt a lifestyle that is generally far different from what family members would otherwise choose. Educators can help families understand that they are not to blame for their child's disorder. They can also help the family understand the implications of autism, link them to support systems, and help them understand how to implement at home interventions that are successful in the school setting. Families, in turn, can help educators understand idiosyncrasies of their child as well as techniques that have been useful in the home environment. The student ultimately will benefit from a cooperative and mutually supportive effort between educators and families.

Characteristics of Autism

The diagnostic criteria for autism have changed somewhat since those detailed by pioneer Leo Kanner (1943). The changes have reflected evolving concepts of the disorder, and have not been universally accepted (Szatmari, 1992). The DSM-III criteria (American Psychiatric Association, [APA], 1980) were criticized as too restrictive (Volkmar, Cohen, & Paul, 1986), while Szatmari (1992) suggested that the DSM-III-R (APA, 1987) criteria may lack specificity, and thus incorrectly overidentify students as having autism.

While the subtleties of the criteria for autism are debated, authorities agree that three areas of developmental difference exist. Wing (1991) noted that "both the World Health Organization (WHO) and the American Psychiatric Association (APA) emphasize the importance for the diagnosis of impairments of social interaction and communication and the presence of repetitive stereotyped routines" (p. 105). Additionally, Rutter and Schopler (1988) stressed that it is the deviance in the developmental process that sets autism apart from other disorders. Impaired language and socialization may be found in mentally retarded individuals or children with communication disorders, yet, while those individuals may demonstrate delay, they do not demonstrate the pattern of deviance that is distinctive to autism. Individuals with mental retardation or communication disorders also are unlikely to have significant repetitive stereotypical routines. Students with schizophrenia may show an assortment of bizarre behaviors but not the same deviance of language and social development that is characteristic of autism (Rutter & Schopler, 1988).

Impairment in reciprocal social interactions. Of the three characteristics of autism, several authors indicated that the qualitative impairment in reciprocal social interactions is the essential feature of the disorder (Frith, 1989; Gillberg, 1990). Kanner (1943) suggested that children with autism were happiest when left alone to engage in solitary activities. Young children with autism may not respond differentially to strangers and may act as if people, including their own parents, are not important. This contrasts markedly with the importance of social relationships for most children. It also contrasts with the sensitivity displayed by many children with autism to very small changes in their physical environment or in their routines. Social impairments can take many forms, and include a lack of awareness that others exist (for younger and lower functioning students) to interacting with others only in terms of the child's own obsessive interests (a characteristic demonstrated by older, less impaired students). The DSM-III-R (APA, 1987) delineates examples of how this impairment in social interactions is manifested; however, the key issue is not just that children with autism are socially isolated, but that they are very limited in the degree they are able to modify their social behavior to meet the demands of the environment (Gillberg, 1990).

Impairment in verbal and nonverbal communication. A second important feature is impairment in verbal and nonverbal communication (Gillberg, 1990). Some individuals with autism never develop speech (Paul, 1987), but even students who become verbally fluent have significant receptive and expressive communication differences. Kanner (1943) indicated that children with autism fail to use speech for communicative purposes. He also commented on the echoic repetition of whole phrases, pronominal reversals, primarily involving the child's reference to him or herself as "you," and of a literalness in interpretation (Kanner, 1943). Some very capable students with autism demonstrate more subtle communication deficits than those described by Kanner. They may exhibit large vocabularies and reasonable grammar. Some are described as talking like grownups in early childhood, although they tend to ramble. Very able students with autism are referred to as high-functioning. The term ***high-functioning*** describes individuals who have a diagnosis of autism and who also score within the average range on standardized intelligence tests; the usual intellectual quotient cutoff score mentioned is about 70 on either a verbal or performance measure (Szatmari, 1991; Yirmiya & Sigman, 1991). For high-functioning individuals with autism, initiating and sustaining a conversation seems to be especially problematic. Language is used not for social interaction but as a means to a particular concrete end (Szatmari, 1991). Additionally, the speech of very verbal high-functioning individuals with autism, sometimes referred to as having Asperger's syndrome, is characterized by a lack of inflection in sentences, and conversation that is tangential, off the point, and circumstantial. Because few links are provided among thoughts in a conversation, the overall effect lacks cohesion (Szatmari, 1991).

Restricted repertoire of activities and interests. The third area of deviance that must exist for a student to be diagnosed as having autism concerns markedly restricted, repetitive, and stereotyped patterns of behaviors and interests (APA, 1987). The meaning of the tendency to impose rigidity and routine on a wide range of everyday occurrences remains obscure, and the ways in which the stereotypical patterns are evidenced vary (Rutter & Schopler, 1988). They may be reflected in distress over changes in small details of the environment, stereotypical and repetitive motor mannerisms, persistent preoccupation with parts of objects, attachment to unusual objects, compulsive rituals, and a markedly restricted range of interests as well as a preoccupation with one narrow interest. Specific examples of these patterns are detailed in the DSM-III-R (APA, 1987), but it is important to realize that the extreme interest can develop in subjects such as astronomy, meteorology, wrestling, or rock videos. The interests can shade into the interests of normal children. However, while such interests typically are used to interact with others, the individual with autism engages in the solitary interests for the sake of the interests, not as a means to interact (Szatmari, 1991).

The symptoms that comprise the triad of impairments in autism occur on a continuum. Wing (1991) has detailed the continuum concept by providing concrete examples of the manifestations of autism for eight symptoms on a four-point scale, ranging from most severe to least severe. For example, a very severely affected individual would demonstrate no formal language system. The most severe manifestation shades to somewhat less affected individuals who demonstrate limited formal language that is mostly echolalic. That level shades into individuals who demonstrate an incorrect use of pronouns and prepositions and idiosyncratic use of words and phrases. The least affected individuals use grammatically correct language but are long-winded and repetitive, and provide very literal interpretations (Wing, 1991).

BASIC CONSIDERATIONS

It is time to refute forever the notion that autism is caused by psychodynamic conflicts between mother and child! Autism has a biological cause. The exact nature of the cause is not known, but there is evidence for several contributing factors: genetic, pre- or perinatal brain damage, and immune dysfunction and/or viral infection (Frith, 1989). There appears to be no single biological cause, but rather a causal chain that produces varying degrees of harm. The basis of the disorder is important because parents need reassurance that their parenting in no way contributed to their child's having autism.

Role of the School Psychologist

Most, if not all, practicing school psychologists will encounter and serve students with autism. Research has demonstrated that autism occurs in somewhere between four to five children in 10,000 (APA, 1987) to one in every 1,000 children (Frith, 1989). What is the role of the school psychologist in serving these students? First, it may be to recognize students who reflect the triad of difficulties and refer them elsewhere for evaluation, or, if appropriate, base interventions on strategies that would be effective for a child with autism. Recognizing the subtle characteristics in higher-functioning students is especially difficult, but experience matters in making the diagnosis of autism at any level of functioning. Interpreting the significance of different, absent, or delayed behaviors depends on a sound clinical background and experience in autism. Making the diagnosis is not a reasonable expectation for all school psychologists, but recognizing the range of manifestations of autism is reasonable.

A second role for school psychologists is that of assessment. Behavioral assessment is the cornerstone of assessment when working with students with autism. Additionally, Reschly (1990) has emphasized the relevance of assessing adaptive behaviors for all students who are handicapped. It is certainly important to do so for students with autism, and it is vital to do so in adolescence as part of transition planning. The Scales of Independent Behavior (SIB), completed with parents or parent surrogates as respondents, have proved to be particularly helpful. The SIB assesses both adaptive and problem behaviors. It also provides prompts for discussing training objectives that the respondent would like to see implemented in each of the fourteen adaptive behavior areas. Completing the SIB affords an excellent opportunity for the respondent and psychologist to discuss goals and objectives in a structured format. Parents generally appreciate this opportunity to provide input, and a cooperative relationship is fostered.

The third role for school psychologists is that of providing consultation services. Any psychologist trained in behavioral consultation possesses most of the skills required to help in the classroom and at home. Consultation skills and a willingness to be of service are the only requisites to working with students with autism. An increased understanding of autism and training in the strategies and techniques that have proven to be helpful with these students do, however, increase the effectiveness and ease of interventions.

BEST PRACTICES

Schopler and Mesibov (1988) stress that children with autism perceive the world differently than do the majority of the population. To help them adapt, educational approaches should acknowledge and accommodate those differences. Students with autism have significant deficits in comprehending language (Cox, 1991a), so it is important to provide visual cues. Schopler and Mesibov (1988), like other teacher trainers and professionals in the field of autism, also discussed the fact that students with autism respond well to structure. Landrus and Mesibov (1986) operationally defined the important components that lend structure to the classroom environment while providing the visual cues that students with autism require. The components provide an approach to teaching students with autism that helps reduce behavior problems while developing independence in the students: Structured Teaching.

Structured Teaching

The student with autism will have fewer behavior problems and experience greater independence and success if the classroom is structured and organized and provides visual cues that help make expectations clear. The structure, organization, and visual cues are provided by Structured Teaching. Structured Teaching uses physical organization, scheduling, and specific teaching methods to promote success. While it is important to emphasize crucial elements of structure, all aspects of a student's environment and educational program are tailored to the needs of each student (Landrus & Mesibov, 1986).

Physical organization. The physical arrangement of the room can help a student be more independent and more compliant. Students with autism often have serious organizational problems and, because of comprehension difficulties, may not understand rules or directions. Additionally, most are very distractible. The physical organization of the classroom can help with these problems. Lower-functioning and younger students, as well as those with less self-control, will need more structure, boundaries, and cues than higher-functioning and older students. Having specific areas for various learning activities, marking clear boundaries, and making materials easily accessible helps students know where they are to be and permits them to get their own materials (Landrus & Mesibov, 1986).

A classroom for young students requires different areas for play, teaching, independent work, snack, and developing self-help skills (Landrus & Mesibov, 1986). A classroom for older students who require a special education classroom for much of the day typically has a leisure area, a work area, a domestic skills area, a grooming area, and places for individual teaching (Landrus & Mesibov, 1986). Additionally, classrooms need a place for students to put their personal belongings and an established place for the teacher's desk. Large rooms with totally separate areas for each activity are the ideal, but are uncommon. However, the key is to use visual cues to make expectations clear. If a room contains one table and it must serve multiple purposes, then it is important for the student to be able to discriminate visually each activity. For snack time there could be a sign that says "Snack" and a tray with the students' drinking glasses on the table. Art time at the same table could be differentiated by a sign saying "Art" and a pile of protective shirts that would subsequently be worn by the students. It is a good idea to provide the printed word and another visual cue that can be understood by nonreaders. Labeling the environment gives students with autism the opportunity to acquire reading skills in a very natural and meaningful way, and some children with autism learn to read and write before they communicate verbally.

In establishing the different areas in a classroom, consider the natural attributes of the room. Children with autism are distractible, so independent work areas need to minimize distractions. Having the desk face a blank wall can be effective, as can providing the student with a study carrel. Landrus and Mesibov (1986) also point out that "areas where students spend some independent time, such as play or leisure, are better off not being located near exits. This can take away a bit of worry about student 'escape' from the teacher's mind" (p. 3). The play area for younger children requires clear and sturdy boundaries that provide a safe environment for energetic little people. Play area boundaries can include walls, shelves for toys, or child-sized pretend sinks and appliances. Because of the nature of activities in a play area, boundaries need to be sturdy. In other areas, clear visual cues are often all that is needed. Rugs or tape on the floor can let a child know where he or she is to sit for story time or where to stand for washing hands or dishes. For the student with autism in a regular education classroom, a bit of tape can help him or her understand where to form lines or sit during group times. Another accommodation that can be helpful to the student in a regular education classroom is an additional desk for independent work. The student sits in a desk with classmates for group instruction and activities but can go to his or her other desk, situated to minimize distractions, to complete assigned tasks.

Schedules. Schedules and routines are both important because they provide a student with structure, understanding, and predictability. Classroom routines are good, but are not a substitute for schedules. Checking the daily schedule should become part of the student's routine; it is the schedule that provides flexibility. Students with autism typically do not accept changes in routine well, yet the day-to-day activities in classrooms do change. The student with autism will be able to accept those changes more easily if checking a schedule has become part of the student's routine, if the changes are on the schedule, and if the schedule is at a communication level that matches the level of the student.

We all depend on our personal schedules; they tell us who we are to see, what we are to do, where we are to be, and when we are to be there. The use of schedules for students with autism basically has the same function, but the communication system can vary. High-functioning students who read well are good candidates for written schedules. Students who do not yet read fluently benefit from a pictorial representation. The picture can be a line drawing (artistry is not critical — stick figures are very adequate) or a photograph, usually used with younger children who are learning the concept of schedules. The lowest level of schedule is an object schedule. The object schedule is helpful for young students, who must first learn that an item in hand can represent an event that will occur.

Children are often first started on an object schedule; they then move to a photo schedule, and the photo is frequently combined with a word, called a photo/word schedule. The next step is the line drawing schedule, again often combined with a word. Finally, there is the word system, similar to what we all use in our daily lives. An example of this progression would be to start by handing a child a diaper, to indicate that it is time to change a diaper. For a child on a picture schedule, a photo of the speech pathologist could indicate that it was time for speech, while a line drawing of a sink and dishes could indicate that it was time to do the dishes. The schedule that seems easiest for the teacher is the written word, but the system is supposed to enable the child to be independent. Thus, however tempting it may be, a written schedule should be used only when the student reads well.

Many classrooms use two types of schedules simultaneously — a general class schedule and an individual student schedule (Landrus & Mesibov, 1986). The general class schedule indicates what the teacher has planned for the entire class, while the schedule for an individual student would also note when the child was to see the speech pathologist and specifically what that child was to do.

Schedules can be individualized in many ways. As noted already, there are object schedules, two kinds of picture schedules, and written schedules. Schedules also differ in the time period they span. Some schedules list activities for the entire day, while others deal with short spans of time (Cox, 1991b). An example of the use of schedules for a young student might be to have the child's individual schedule on a clipboard he or she carries. The child's routine has him or her first put coat and book bag away and then check the schedule. The schedule might have a photograph of the play area first, so the child could turn that picture over and proceed to the play area. At the end of free play the child would be told again to check the schedule. The next photograph might be of the work station. Again, the child would turn the photograph over and go to the work area. At the student's independent work area there might be a strip of poster board with colored geometric shapes clipped to it in a vertical row. The student learns to take the topmost shape and match it to the same shape basket on work area shelves by his or her desk. The shape is turned over to indicate completion, and the basket is replaced on the shelf when the child has completed each task; this process is continued until all the shapes have been turned. The child then checks the schedule and finds a picture of the computer, so proceeds to the computer (a very much preferred activity).

An important point of good scheduling is the alternating of less preferred and more preferred activities. This employs the Premack principle, where the opportunity to do more preferred activities is contingent upon the completion of less preferred activities. The Premack principle, or First/Then sequencing, is a powerful way to maintain motivation in students. A final point about scheduling is that children need to be taught to use schedules.

Teaching methods. Teaching methods involve the use of visual cues to provide directions and prompts to the student (Landrus & Mesibov, 1986). In American classrooms, directions are usually given verbally; for the student with autism they also need to be given visually, at least to a large degree. Most important, directions always need to be given at the student's level of understanding. For example, to a child with limited expressive language, do not say "I want you to finish coloring the picture, and then when you finish, you can go select a game to play on the computer." Instead, minimize words, which can be confusing to the student with autism, and say, "First finish picture, then computer." Verbal directions should be accompanied by gestures and visual cues to help the student understand (Landrus & Mesibov, 1986). In the example above, the teacher could show the student the same picture, already colored, point to the child's uncolored picture, then point to the computer. Using gestures, as verbal directions are being given, helps the student with autism understand.

An important aspect of giving directions is having the student's attention prior to giving the direction (Landrus & Mesibov, 1986). For a student with autism this does not mean that eye contact must be established, but it does mean that the student needs to signal attention. That may be accomplished by body orientation, a verbal response, or by stopping other activities. "When giving directions, a teacher needs to make sure that expectations and consequences are clear and organized for the student. If a student does not know where materials are, how to start a task, or what to do when he is finished, then he is not likely to perform a task up to teacher standards" (Landrus & Mesibov, 1986, p. 9).

There are many ways to use visual cues and organizational strategies to help students with autism understand what is necessary to complete a task. For an adolescent, a laundry basket with several items of clothing to be ironed and an iron and ironing board convey quite clearly that ironing needs to be done. The goal is always to convey visually to the student four things: How much work? What work? When is the work done? and What is the reward for doing the work? (Landrus & Mesibov, 1986; Cox, 1991b). The laundry basket example clearly conveyed the first three things. Adding a picture of a can of pop or a computer would also indicate the reward. Organizational strategies that are helpful include working from right to left and from top to bottom (Cox, 1991b). Those strategies are equally applicable to washing floors, cleaning mirrors, vacuuming, reading, or doing work sheets.

As demonstrated with schedules, visual cues can be provided at several different levels. If one wanted to convey to a high-functioning teen all that needed to be done to clean a bathroom at home, a written list could be provided, and the student could check off each item cleaned. For a student not able to read, the same thing could be achieved pictorially by having a photo or line drawing of the mirror, sink, tub, toilet, and floor. An alternative, for a student who had previously learned a cleaning routine and who needed minimal prompting, would be to put the containers of glass cleaner, scouring powder or solution, toilet bowl cleaner, a detergent for the floor, and sponges all in the bathroom that was to be cleaned.

Visual cues are very helpful for students with autism, but these students still need direct instruction for new tasks. The visual cues help them to organize, sequence, and stay focused, but tasks need to be taught to the student with autism. In teaching tasks, or the use of visual cues, prompts help assure accuracy. A physical prompt involves physically assisting a student through the motions of the task; a visual prompt can take a variety of forms. It might be a plate, knife, fork, spoon, and drinking glass drawn on a placemat to assist in table setting, a list of two or three rules taped to a student's desk, or a gesture to point out a spot remaining on a mirror being cleaned. The final level of prompt is verbal. In using prompts, or giving other directions to students, you want to tell them what to do, not what not to do. Thus, if a rule were taped to a student's desk reminding the child not to swear, it should say something like "Use appropriate language." Prompts need to be clear, consistent, and directed to the student before an incorrect response occurs (Landrus & Mesibov, 1986). If a student used too much detergent when preparing to wash dishes, it is not helpful to say, "No, you used too much detergent. Only use a little next time." Far better is to say, as the student picks up the detergent on the next occasion, "Use only a little detergent, just enough to fill this lid." Then give the student a way to approximate the amount and help him or her measure the soap accurately. After several days of that sort of prompting, the student will be independent at the task (Landrus & Mesibov, 1986).

Students with autism need visual cues and structure. However, there are other programming considerations. School psychologists routinely work with teachers to target behaviors for change. In working with students with autism, special attention is warranted in selecting and prioritizing behaviors. For behaviors that are a part of autism and that are not a high priority in the developmental sequence of skill acquisition nor critical to the student's functioning, it may be appropriate to delay targeting the behavior, and instead focus on the most critical skills. Cases where target behaviors might be delayed include lack of eye contact in a young student or harmless and discrete self-stimulatory shirt rubbing in a low-functioning student. Additional programming considerations include the following general needs of young and lower-functioning students with autism: small classrooms; a curriculum designed to enhance communication skills; special training in leisure and prevocational skills; the appropriate use of behavior theory for managing behavior problems — especially an emphasis on an environment structured to promote success and on reinforcement of positive behaviors, rather than punishment of negative behaviors; and attention to problems of generalization (Schopler & Mesibov, 1988).

All students with autism need interventions to improve their adaptive skills and reduce symptoms that limit participation in normal activities. Rutter (1985) has suggested that it is not helpful to adopt a rigid response to diagnostic labels — to assume that because a child is diagnosed as having autism, the only suitable educational placement is a unit for other children with autism. Instead, Rutter (1985) and Szatmari (1991) believed that it is critical to maintain higher-functioning students in situations where they are integrated with nonhandicapped students. Szatmari (1991) indicated that a program without integration would produce very slow progress and perhaps inappropriate behavior. However, he cautioned that integrations require careful planning and extra resources. Szatmari (1991) discussed the educational programming needs of high-functioning students with autism more specifically by noting "areas that may require intervention include training in socialization, communication, and imagination, adaptive skills, and controlling aggressive behavior" (p. 89). Experience suggests that a wide range of students with autism can be integrated successfully into regular education classes by employing structure and visual cues.

Behavior Management

The management of behavior is a part of all teaching, and teaching children with autism is no exception. But there are some different considerations in working with children with autism. Behavior modification techniques look at antecedents to a behavior but typically focus on the consequences of a behavior. For students with autism, the focus needs to be on the antecedents to the behavior and skill deficits that can characterize autism. If such a student has tantrums, it may be because of the receptive or expressive communication deficits; consequently, the intervention should focus on giving the student a more functional communication system. If a student with autism were not handing work in to the teacher, it would be important to consider the possibility of both an organizational problem and a social/communication problem. Some students with autism have difficulty initiating an interaction with the teacher to hand in an assignment. If that were the case, the only needed intervention might be to provide a basket where the student could place completed papers. Lots of praise and a corrective "no" with redirection are important techniques to influence the student with autism or any student. Certainly, positive reinforcement and mild punishment are effective strategies for students with autism (Schopler, Reichler, & Lansing, 1980). But for the student with autism, the focus of interventions needs to be on providing adequate structure and visual cues while understanding how autism may be affecting behavior.

Social Skills Training

Gresham (1990) has established the need to do social skills training for handicapped students, while Wooten and Mesibov (1986) have discussed that need in students with autism. Because the general topic of social skills training is thoroughly discussed by Gresham (1995) in this book, comments here are limited to those that pertain directly to working with students with autism. Students with autism have more trouble generalizing social skills than do other students, so social skills training with this population should focus on the generalization of skills. I have found it effective to positively reinforce the targeted skill(s) across several settings, in a cooperative effort with teachers, the speech pathologist, and parents. The additional efforts in assuring generalization of skills has meant that fewer skills, typically only four to six, were targeted in a year.

Wooten and Mesibov (1986) have used nonhandicapped peer tutors to do social skills training. Their approach, which met with success, also enhanced the generalization of skills. Cox and Schopler (1991) have emphasized that one of the major benefits of programs that use peer tutors is the change in the peer tutors. They note "one quickly develops an appreciation for the change in peer tutors' sensitivity to, acceptance of, and openness with their paired handicapped participant" (1991, p. 908). To improve the skills of the student with autism while helping nonhandicapped peers gain sensitivity and acceptance would be ideal!

Facilitated Communication

Facilitated communication (FC) is included in this section because an awareness of it is vital for psychologists dealing with students with autism. Basically, the technique involves a facilitator supporting the hand, wrist, elbow, or shoulder of the person with autism, or other disability, while he or she selects letters on a letter board, computer keyboard, or typewriter. The facilitator initially may help isolate the index finger and stabilize the hand of the person being assisted, but is not to aid in letter selection. The ultimate goal is to fade the use of the facilitator so the student is able to type independently (Wheeler, Jacobson, Paglieri, & Schwartz, 1992). The technique was pioneered in Australia, but has been refined in this country and enjoys a great deal of support from many enthusiastic parents and educators (Saks, 1992). However, research examining the validity of FC is less glowing than are the anecdotal reports. The research supports two major conclusions. First, it makes it "fairly clear that at least some, and possibly many, facilitators are unknowingly influencing (or producing) the communications that they believe to represent the individual's free expression" (Wheeler et al., 1992, p. 3). It is important to note here that there is no evidence that facilitator influence is purposeful or intentional! Second, some people do clearly benefit from FC and become skilled in independent, unassisted typing (Wheeler et al., 1992). The benefit to these individuals is clear. Additionally, "there may be secondary gains for people from increased socialization with facilitators, and perhaps, among peers if conversations are facilitated with peers" (Wheeler et al., 1992, p. 3).

This is currently one of the most controversial topics in the field of autism, if not the most. No one wants to deny a child every opportunity for success, yet no one wants to raise false hopes. The conclusion of the research — that FC helps some individuals become skilled, independent typists — raises a related point. Whether through FC, trial and error, keyboarding or typing classes, or independent study, typing skills and use of a computer can make an enormous difference in the written communication skills of high-functioning students with autism. The written language skills of many of these students are a problem, for various reasons. However, many have significantly improved their fluency and technical adequacy when allowed to do writing assignments on the computer. Additionally, they have become less averse to writing; some even have found pleasure in it.

SUMMARY

Autism is a biologically based disorder that is characterized by qualitative impairments in reciprocal social interactions, qualitative impairment in verbal and nonverbal communication, and a markedly restricted repertoire of activities and interests.

The problem-solving approach is very effective in dealing with the difficulties faced by students with autism. However, in planning interventions, one must make sure that the classroom environment provides the structure and visual cues that are necessary accommodations for the student with autism. When behavior problems do occur, skill or performance deficits that are characteristic of autism may be the cause. In those cases, sometimes a skill, such as a different communication system, should be taught. At other times — such as with the student who would not initiate contact with a teacher to hand in assignments — a performance deficit can be overcome by finding a way to achieve the goal in a different manner. An alternative strategy would have been to positively reinforce compliance and mildly punish noncompliance; but in working with students with autism, it is preferable to save that strategy and use it only when an alternative strategy is not available. Finally, there are some behaviors that are a part of autism and not a priority in the developmental sequence of skill acquisition. The lack of eye contact in a young student with autism might well be such a behavior. It should be addressed at some point, but might not be a high-priority behavior to target immediately.

Most, if not all, practicing school psychologists will encounter and serve students with autism. The school psychologist has the skills to be of service to these intriguing students and their families.

Best Practices in Working with Children with Psychosis

Thomas J. Huberty
Indiana University

OVERVIEW

The terms *psychosis* or *childhood psychosis* refer to a group of psychological/psychiatric disorders that are considered to be the most severe forms of disturbance in children. For the professional, psychosis likely epitomizes "serious emotional disturbance" because of the type and extremes of behavior shown and the degree of impact that behavior has on the social, personal, family, and academic functioning of a child. Children with psychosis present behavioral, academic, and developmental challenges to parents, schools, and others in the attempt to meet their unique needs. This chapter will provide an overview of childhood psychosis with emphasis on describing its characteristics, what the school psychologist should know about working with these children, and suggestions for using a problem-solving approach to develop intervention approaches.

Childhood Psychosis as a Form of Developmental Psychopathology

The traditional approach to understanding children's abnormal behavior, including psychosis, emphasizes a medical model — i.e., one in which the locus of the problem is within the individual — and "look(s) to statistical norms, social rules and values, or various conceptions of ideal psychological adaptation to define standards of normality. Marked deviations from these standards are labeled as pathological or dysfunctional" (Cowan, 1988).

Conversely, *developmental psychopathology* emphasizes the development and change in behavior of the individual over time and factors that place him or her at increased risk for behavioral and emotional problems. Thus, even though a child might be diagnosed as psychotic at one point in time, it is conceivable that the diagnosis might change later, or that the diagnosis might remain but some of the initial behaviors might change or disappear. Developmental psychopathologists are interested in observing and studying changes over time, and do not view the child's behavior as static but as mutable, being a function of developmental processes and interventions designed to address problem areas. Childhood psychoses represent disorders that will persist throughout life, so the major focus of school psychologists is on the personal, academic, social, and family needs of the child over time. For further information about developmental psychopathology, the reader is referred to Achenbach (1982), Lewis and Miller (1990), and Nannis and Cowan (1988).

Characteristics of Childhood Psychosis

For many years, childhood psychosis comprised the disorders of schizophrenia, infantile autism, symbiotic psychosis, and severe, psychotic depression. It was not until Kanner (1943) described autism as a unique disorder separate from schizophrenia that efforts were intensified to more clearly define the nature of childhood psychosis. Currently, autism is considered to be a developmental disorder, although some of the behaviors may be similar to those seen in schizophrenia. Mahler (1952) described *symbiotic psychosis* as a unique disorder characterized by the psychotic behaviors of intense clinging to the mother, extreme emotional reactions when separated, and little personal identity. However, research has failed to support this distinction, and currently it is not considered to be a separate diagnostic category. Manic-depressive psychosis (now called bipolar disorder) also might be viewed as another category, but this disorder is rare in children and adolescents. Other disorders designated as psychotic (e.g., schizophreniform disorder) or having psychotic features (e.g., major depressive episode) also may occur in less frequent cases. Merrell (1994) includes three Axis I disorders described in the *Diagnostic and Statistical Manual of Mental Disorders*, 3rd ed., rev. (DSM-III-R; American Psychiatric Association, 1987) as representing psychotic disorders that might be seen in childhood or adolescence: schizophrenia, delusional (paranoid) disorder, and Psychotic Disorders Not Elsewhere Classified.

The DSM-III-R does not include a separate category for childhood schizophrenia in "Disorders Usually First Evident in Infancy, Childhood, or Adolescence," although the criteria for adult schizophrenia may be applied to children (p. 27). The DSM-III-R does not, however, apply the term *psychosis* to children's disorders but categorizes them as pervasive developmental disorders (PDD). The stated rationale for this global classification is that only autism has been defined as being a subgroup of PDD, and that childhood psychoses are not related to adult psychoses. The three major characteristics of PDD are "qualitative impairment in reciprocal interaction," "impairment in communication and imaginative skill," and "markedly restricted repertoire of activities and interests" (p. 34).

If adult criteria are applied to childhood psychoses, the characteristic symptoms are dysfunctions in the following areas:

- *Content of thought:* Delusions that may be multiple, fragmented, or bizarre.
- *Form of thought:* Loosening of associations, incoherent or tangential speech shown, or speech that shows poverty of content or communicates little information.
- *Perceptual disturbances:* Hallucinations; sensations of bodily change; hypersensitivity to sound, sight, and smell; illusions; synesthesia.
- *Affect disturbances:* Flat or inappropriate affect.
- *Sense of self disturbances:* Lack of feelings of individuality, uniqueness, and self-direction.
- *Volition:* Disturbance in self-initiated, goal-directed activity.
- *Impaired interpersonal functioning and relationship to the external world:* Difficulty with interpersonal relationships.
- *Psychomotor behavior difficulties:* Marked decrease in activity, spontaneous movements, and reactivity to the environment.

Clarizio and McCoy (1983) provide a list of "clinical manifestations" that are secondary characteristics of children with psychosis: bizarre body movements; repetitive, stereotypic movements; distorted use of body parts; nonhuman behaviors such as making animal noises; disturbances in speech structure and content; denial of the human quality of others; inappropriate affect, ranging from rather flat to explosive; special interest in a particular object or activity (such as remembering detailed statistics on sports figures); and a distorted sense of time, including difficulty in separating the present from the past or the future (pp. 360–361).

Rosenhan and Seligman (1989) differentiate Type I and Type II schizophrenia. Type I is described as manifesting "positive symptoms" — e.g., delusions, hallucinations, and prominent thought disorders — which are reversible. Type II is described as showing "negative symptoms" — e.g., flat affect, poverty of speech, and loss of volition — which are not amenable to change. Type II schizophrenia has a much poorer prognosis than does Type I, and is associated with challenging, long-term care needs.

Cullinan, Epstein, and Lloyd (1983) list other characteristics associated with childhood schizophrenia:

- Ratio of 3:1, male to female
- Occurrence of about 1 in 1,000 live births
- Generally, low-average level of intelligence
- Earlier age of onset more likely to be associated with mental retardation
- Likelihood of a family history of schizophrenia, which may include a genetic basis
- Tendency to come from lower socioeconomic backgrounds

There have been many theories about the causes of childhood schizophrenia (including unresponsive and unattached mothers, chaotic environments, and neurological/neurochemical abnormalities), which are too extensive for discussion here. The predominant research suggests that the causes of most psychoses likely are based in neurochemical imbalances, specifically disruptions in neurotransmitters such as dopamine. Other theories suggest that there may be a specific gene or set of genes that lead to schizophrenia, or that an individual has a genetic predisposition for schizophrenia that emerges only when particular stressful conditions occur (i.e., the diathesis-stress model) (Rosenthal, 1970). Regardless of the causes of childhood psychosis, the most practical considerations for the school psychologist or other professional will involve working to improve the child's social, behavioral, and academic functioning.

BASIC CONSIDERATIONS

Impact of Childhood Psychosis

Academic performance. Children with psychosis often achieve less in most subject areas than their peers. Success in many school tasks requires sustained attention, concentration, and interest in objects and events beyond oneself, which are some of the abilities that the child with psychosis often lacks. Although the measured intelligence of these children can range from retarded to superior levels, most show lower than average ability. Performance in the classroom on a daily basis can be problematic, due to difficulties in responding to abstract material, receptive and expressive language problems, and lesser ability to participate. Most of these children receive special education services during their educational careers, either in separate classes or on a consultation basis. In general, children with schizophrenia or other forms of psychosis tend to be difficult to teach and to have learning problems (Clarizio & McCoy, 1983).

Interpersonal relationships. Perhaps the most salient aspect of children with psychosis is that, invariably, they show significant deficits in interpersonal relationships. They have difficulty in social situations, may make inappropriate comments, show stereotypic or ritualistic behavior, treat others as objects, exhibit perseverative behavior, withdraw from social situations, or demonstrate self-stimulatory behavior. They fail to perceive the subtle nuances of interpersonal situations or to make appropriate inferences or interpretations of the actions or words of others. Children with psychosis may show a preference for inanimate objects over peers and adults, and they may treat others primarily as instruments for meeting their needs, exhibiting little emotional attachment to them.

Family factors. Although early theorists tended to ascribe the causes of childhood psychosis to parents who were hostile, rejecting, or detached from the child, there is little evidence to suggest that children develop psychosis as a function of parental behavior. It is possible, however, that how these children are treated within the family may exacerbate their problems. In general, children with psychosis present a myriad of challenging behaviors that can have significant impacts on family functioning. In addition to unusual behaviors, they may have deficits in self-help skills, thereby requiring added attention in day-to-day activities. These children also may show social withdrawal, temper tantrums, needs for sameness, poor social skills, and concrete modes of thinking that contribute to stress among family members. If the parents or family members are unable to develop effective ways to cope with these behaviors and their effects, then problems are likely to become more complicated.

Areas of Emphasis for the Child with Psychosis

As indicated above, children with psychosis show a variety of maladaptive behaviors that may interact in complex ways. To effectively work with these children, the school psychologist must be able to assess and delineate the child's needs in four areas of functioning: personal, social, academic, and family domains. Personal assessment includes addressing the child's emotional and behavioral functioning within various settings. Knowledge of the level of cognitive development, language skills, overall adaptive behavior, motor skills, affective development, and school functioning is essential. Because the social functioning of children with psychosis invariably is impaired, it is important that a thorough knowledge of a child's social strengths and weaknesses be obtained. Obviously, school is an important part of children's lives, and intervention programs should consider the complexity, uniqueness, and challenges associated with psychosis. Family assessment often will be needed, because what happens at home may be manifested at school. In practice, there almost always will be an interaction among these four factors that creates unique challenges for those who work with these children.

Knowledge and Skills Needed by the School Psychologist

Principles of developmental psychopathology. As indicated above, knowledge of principles of developmental psychopathology will be helpful for the school psychologist in working with these children. For the child with psychosis, intervention should be based on the assumption that the child has the ability to progress in one or more developmental areas rather than on the assumption that psychotic processes are static and subject to little change. Although it is true that the progress of children with psychosis often is very slow (Achenbach, 1982), the well-informed school psychologist will focus on the need to help the child develop, regardless of a formal diagnosis.

Medications. Although medications are not used in every case, some children with psychosis are given psychotropic medications, such as antipsychotics or major tranquilizers. These medications may be given to reduce agitation, anxiety, hallucinations, aggressiveness, or other symptoms. Howlin and Yule (1990) suggest that medications may be essential to help prevent relapses that tend to occur with psychosis. The school psychologist should be aware of the general categories of these drugs, their intended effects, and possible side effects. It may be that the school psychologist will be the only person in a school system with the background and training in behavior disorders who can serve as a link with the prescribing physician and report changes in behavior or evaluate medication effectiveness. If the school psychologist is working with a child who is taking psychotropic medications, she or he should become familiar with the specific medications and their associated effects.

Assessment and intervention techniques. The preceding discussion points out that working with children having psychosis is a multifaceted process that requires high levels of individual skills and collaboration with others. The school psychologist should be thoroughly grounded in behavioral and developmental assessment, behavioral approaches to intervention, consultation skills, working with families, counseling, and working with community agencies and professionals. These areas will be discussed in more detail below.

BEST PRACTICES

Behavioral and Developmental Assessment

Because the characteristics of childhood psychosis often overlap with those of children having mental retardation, autism, organic brain dysfunction, or pervasive developmental disorders, it is important that the school psychologist have a background in the characteristics of these disorders. More specifically, the practitioner should have knowledge of how to conduct a functional assessment on the basis of the presenting behavior pattern, using a variety of assessment procedures including systematic observation, structured clinical interviews, educational assessment, objective personality measures, behavior rating scales, various self-report measures of specific problems, adaptive behavior scales, and developmental and family histories.

Of particular value will be thorough assessment of adaptive behavior, using instruments such as the Vineland Adaptive Behavior Scales (Sparrow, Balla, & Cichetti, 1984) or similar measures. The various domains of adaptive behavior will provide a more complete picture of the child's strengths and weaknesses, from which interventions may be developed. Although many of these children have been identified as having psychosis by the time they enter school, the school psychologist may need to make a comprehensive assessment or differential diagnosis. A differential diagnosis that results in a label may not have direct relevance for intervention, but may help to facilitate communication among the persons involved.

When conducting a psychological and educational assessment, the psychologist should emphasize multimethod, multitrait, and multisetting approaches (Martin, Hooper, & Snow, 1986). Multisource/multi-informant assessment also will be needed, because much of the information must come from third parties. The assessment should include this variety of approaches to ensure that sufficient information is gained prior to developing interventions. Determining the needs of these children often will depend upon observation, reports from others via structured or semistructured interviews or behavior ratings, and anecdotal/historical information.

Of particular help in this area are behavior rating scales, especially those that can reliably measure both internalizing and externalizing characteristics. The Child Behavior Checklist (CBCL; Achenbach & Edelbrock, 1983) is especially useful for assessing these children, because it identifies specific behavior patterns and their severity for children aged 2–18. Although it is not specifically designed to assess psychosis, the CBCL does contain items and subscales that may be related to the behavior of the child with psychosis, such as hearing voices (Merrell, 1994). Further, the CBCL has forms for both teacher and parent, thereby reducing the variance associated with using different instrumentation for these informants. Generally, data generated that can be compared across settings and informants will have the most utility.

A related objective inventory that can be completed by a parent or other informed person is the Personality Inventory for Children (PIC; Wirt, Lachar, Klinedinst, & Seat, 1984) that assesses behavior for ages 3–16. The PIC is a multidimensional measure of psychopathology and contains scales having both internalizing and externalizing items. Among the scales are Psychosis, Anxiety, and Depression, which can be valuable in assessing multiple facets of children with psychosis.

Observation of the child in a variety of settings is important to determine how the child functions in different settings and to understand better what environmental variables tend to have a positive or negative effect on the child's behavior. The child with psychosis may engage in unusual behaviors to such an extent that functioning is impaired. Therefore, interval, frequency, or duration recording will be valuable for generating baseline data about the child's functioning, and also can be used to verify data from interviews and behavior ratings.

Although there are a number of self-report personality measures available for depression, anxiety, and so forth, their utility with these children may range from none at all to moderate usefulness (Merrell, 1994). Language problems, concentration difficulties, inability to reflect on internal mood states or behavior, or perseveration with the same answer to several items are but some factors that may lead to invalid results. If self-reports are not appropriate, then observation, behavior rating scales, interviews, and anecdotal records will yield the most useful information.

Standardized achievement tests, while indicating overall achievement, may have relatively little utility for the classroom. More precise information about academic strengths and weaknesses may be gained from evaluating classroom performance and using curriculum-based measurement (CBM) in specific subject areas. The reader is referred to Shinn (1989) for more information about CBM.

Intervention Techniques

Because the child with psychosis often demonstrates needs in many areas, the school psychologist should have a broad background in various intervention methods. Skills in remediation of academic deficits, particularly as related to language skills, are essential. If the child shows language-related deficits in areas such as reading and spelling, consultation with the teacher and the school speech/language therapist may be indicated to develop strategies to address these problems. Language arts and mathematics may be particularly difficult for the child, because of the complex skills required and the need for sustained effort and concentration.

Knowledge and skill in behavioral interventions will be essential in working with these children. The most promising documented interventions for the behaviors shown tend to be operantly based, and may include variations of behavior modification, such as reinforcement methods, token economy systems, and the use of extinction methods for undesirable behaviors. These methods have been shown to be effective in enhancing eye contact, reducing stereotypic or repetitive behavior, increasing completion of tasks, enhancing prosocial skills development, and decreasing self-abusive or self-stimulatory behavior.

Cognitive-behavioral interventions refer to methods of cognitive behavior therapy (CBT) to modify thinking and problem-solving processes, and include self-instructional training, problem-solving, and self-monitoring techniques (Woody, LaVoie, & Epps, 1992). These techniques have been shown to be effective for many academic, behavioral, and social skills problems, and may include procedures such as modeling, self-recording, and self-monitoring. For children with psychosis, however, particular care must be used if CBT methods are to be considered. Woody et al. (1992) suggest that CBT methods are not appropriate for children who have low levels of cognitive functioning as well as difficulty in recognizing their own role, self-efficacy, and personal responsibility in the intervention. Even though a child with psychosis may have average to above intelligence, concreteness in thinking or other cognitive characteristics may render CBT methods of little value, at least in the initial stages of intervention. It is possible that the child might show a negative reaction to CBT, perceiving it as threatening to needs for sameness and structure. The psychologist should consider the developmental appropriateness of CBT for these children, and could do some preliminary trials of these methods before implementing a more detailed plan.

Behavior therapy and behavior modification methods have been shown to be effective with children having psychosis and developmental disabilities. The majority of these techniques can be implemented with children having a range of cognitive and social abilities, including children with psychosis. Several studies have demonstrated the effectiveness of these methods with the behaviors of psychotic children. Many techniques have utilized aversive procedures, which should be used with caution, particularly in a school setting. In general, however, these techniques likely will be the most useful, and can be applied to a number of problems.

Social skills interventions. Because children with psychosis characteristically show deficient social skills, the school psychologist should be prepared to assess and provide intervention in this area. Assessment of social skills can be accomplished by observation, assessment of adaptive behavior, or the completion of scales such as the Social Skills Rating System (Gresham & Elliott, 1990). Another method of assessing social relationships is to gather information about sociometric status (i.e., how the child is accepted by others), such as the system developed by Coie, Dodge, and Coppotelli (1982).

Gresham (1990) suggests that there are four steps in developing interventions for social skills problems: "(a) facilitation of skill acquisition, (b) enhancement of skill performance, (c) removal of interfering problem behaviors, and (d) generalization of trained social skills" (p. 706). Space limitations prohibit detailed discussion of these steps here, but these points should serve as a guide for developing social skills interventions for children with psychosis.

Counseling approaches. In the past, psychoanalytic and psychodynamic therapies were used to treat children with psychosis, on the assumption that the disorders had a psychogenic origin or that alteration of personality processes was necessary for improvement to occur. There is little convincing empirical evidence that counseling and therapy approaches directed toward changing personality processes have been successful with these children. Children with psychosis often lack sufficient self-awareness or ability to reflect upon their behavior or affect to make such intervention helpful. Counseling often is beneficial for families of these children by helping them to reduce the type and extent of behavioral problems shown, and to develop management skills. It can also help to reduce the tendency that some parents have to blame themselves for having a child with psychosis. Applications of techniques of family systems therapy also may be appropriate in some situations. Finally, counseling that emphasizes the child's adjustment in school, personal responsibility, and social relationships may be appropriate.

Variations such as play therapy are not likely to produce significant gains in behavior or development, but may give the child the opportunity to relate to an adult with whom he or she feels comfortable. If used in the school setting, play therapy probably should be viewed as being rather short-term and focused on specific goals. For more discussion of general counseling techniques with children, see Tharinger and Koranek (1990).

Behavioral consultation skills will prove valuable for the school psychologist working with these children. Although there are many models of consultation, the behavioral consultation model proposed by Bergan (1977) or a variation of it probably will be the most useful. Bergan proposes that there are four steps in the behavioral consultation process: (1) problem identification, (2) generation of possible solutions, (3) implementation of the plan, and (4) evaluation of efficacy. Huberty and Skiba (1992) have modified the basic model by including a component whereby the consultee also generates a list of contributing factors to a problem and decides which factors affect the child and her or his behavior. Then the consultee determines which contributing factors are the most salient and can be addressed in developing intervention plans. Following this stage, the last three steps of Bergan's model are implemented. Because there may be many factors operating in the evaluation of and intervention for children with psychosis, it is important to identify as many contributing factors as possible, determine the ones that are the most important and can be addressed, and then develop the interventions.

Perhaps the most challenging task in using behavioral consultation with these children is identifying the problem that is to be the focus of intervention. The problems presented may be complex and have a high degree of interrelatedness (e.g., social skill and cognitive deficits), making it necessary to clearly define the target behaviors while considering other contributing factors. Problem analysis and plan implementation should include consideration of contributing factors, such as the child's cognitive functioning and skill levels to determine the degree to which he or she can participate in and respond to the intervention. Planning evaluation for these children must account for the fact that progress often is slow, uneven, and of a long-term nature, therefore requiring patience and sometimes plan modifications.

Family interventions. When intervening at the family level, it is useful to identify goals, which could include (1) focusing on specific variables or behaviors that are related to or a product of family functioning, (2) enlisting the family's involvement to assist with a problem at school, e.g., task completion, (3) teaching parents how to manage behaviors of the child that are problematic at home or school, and (4) implementing a problem-solving approach for identifying and developing an intervention plan. A variety of interventions could be used, such as family therapy, parent management training, behavior modification, or other approaches. The interventions chosen would be determined by the goals established, the needs of the situation, the characteristics of the participants, the resources available (including family members), and the intended outcomes.

Modifications of curriculum, assignments, and tasks. A frequent method of intervention for children with psychosis has been to place them in special education classes, where they spend most or all of their instructional day. To the extent possible or appropriate, it is best to keep these children in the regular classroom, where they will be more likely to interact with normal peers and imitate desired behaviors. As with any child who has learning difficulties, consideration should be given to modifications of tasks, assignments, and instructions. Breaking assignments into smaller parts, repetition, specific instructions, and task analysis often are necessary. Individual and classwide peer tutoring, buddy systems, and similar peer interaction procedures may be of benefit, depending upon the child's skill levels, behavior, and acceptance by other students.

Liaisons with other professionals and agencies. The child with psychosis may have involvement with other professionals, such as physicians who prescribe medications. The school psychologist can provide valuable services to these professionals by serving as a link with the school. Accumulating behavioral data, observing medication effects, and implementing external recommendations are but some of the roles that are important. If a child has been hospitalized for an extended period of time, working with external professionals to devise plans for reintegration into school can make a major difference in the degree of success and adjustment shown by the child upon reentry. Children who have been away from school for a long time often have readjustment difficulties, which may be exacerbated in children with psychosis. See Colegrove (1990) for a good discussion of reintegration of children into school.

A Problem-Solving Approach

The child with psychosis will present unique challenges to parents and school personnel that likely will require a diversity of approaches toward understanding the nature of the problems and developing effective assessment and intervention approaches. The child with psychosis has a complex interaction among skills and behaviors, unlike problem areas for children who do not have psychosis. Behavioral problems exhibited by the child may have their basis in a variety of causal factors, such as language deficits, social skills problems, or extreme cognitive rigidity. Whereas the behavior problems of nonpsychotic children may be addressed directly, the child with psychosis may require a more complex approach to intervention. For example, a nonpsychotic child with average cognitive ability may respond well to a token reinforcement system for noncompliant behavior, but such an approach might not be effective for a child with psychosis if cognitive and language deficits interfere with understanding or responding to the contingencies or exchange rules. Because assessment and intervention for children with psychosis is complex and challenging, a systematic problem-solving approach is recommended.

The complex nature of these children's problems indicate that a problem-solving approach will facilitate assessment and intervention, and can be conceptualized as a series of steps to be addressed:

1. Identify the child's needs and problems in behavioral terms with adequate baseline data.

2. Prioritize and determine which of the child's needs or problems should be the focus of interventions.

3. Determine the factors that are causing or contributing to the identified problems or needs.

4. Generate possible intervention approaches for the problems.

5. Select the appropriate interventions.

6. Implement the selected interventions.

7. Evaluate the interventions and revise, if necessary.

Identifying the child's needs is accomplished by using a multiple-component approach in assessment, with particular attention to objective, behavioral approaches. At this stage, it is important to be as specific and thorough as possible, because behaviors that will become the focus for intervention will be specified during this assessment. Adequate baseline data should be determined from observation, rating scales, or other objective measures of behavior.

Prioritizing behaviors is a process of determining which behaviors are to be the focus of possible interventions. The primary factors in determining which behaviors to focus on are the degree to which they interfere with the child's functioning (or that of others) and the extent of intervention indicated. For example, the child may engage in self-stimulatory behavior that is not disruptive to the class and also may show frequent aggressiveness. Although the self-stimulatory behavior may be noticeable and annoying, the aggressiveness should be focused on first, because of its impact on the child and others.

Determining causal or contributing factors can be achieved by assessing individual child characteristics, environmental variables (e.g., curriculum), behavior management skills of parents or teachers, and other factors that may cause or maintain the problems. Of particular importance in this step is to determine which of these factors are the most amenable to change. For example, although a child's social skills deficits may be related to cognitive ability, emphasis should be placed upon the area most amenable to change, (i.e., social skills) while considering the impact of the cognitive problems.

Generating possible intervention approaches essentially can be a brainstorming process, i.e., considering a variety of possible interventions that may be appropriate. At this point, there is little attempt to select the best intervention; rather, the goal is to identify potential specific interventions.

Selecting the appropriate intervention should be determined by the specific goals to be accomplished, the resources needed to implement an intervention, the resources available, the degree to which the intervention can be implemented for the specific problems, and the degree to which efficacy can be evaluated. Careful attention to these factors will help to increase the probability of success. For example, timeout would not be chosen to treat withdrawal behavior but might be appropriate for aggressiveness.

Implementing the intervention will occur as the result of developing a clearly delineated plan of action that follows from the baseline data. Implementation should identify what is to be done, who will be responsible for each aspect of the intervention, and the plan for collection of evaluative data.

Evaluating the intervention is the last, but important, aspect of an intervention. By comparing current data to the baseline information, the school psychologist can determine if the intervention should continue or be modified in some way. If changes are to occur in the intervention, it may be necessary to gather more baseline data. An effective method is to do pre- and postintervention observations or behavior ratings that can be compared to determine the changes that have occurred.

SUMMARY

This chapter has focused on children with psychosis and issues regarding provision of quality school psychological services for them. These children present unique challenges to professionals because of the nature of their problems, which will persist through life. The greatest gains for these children likely will be in the educational arena, which is where the school psychologist can be of the most help. Particular areas of importance are improvement in social skills, interpersonal relationships, personal care and responsibility, and academic functioning. The practitioner should have knowledge about developmental psychopathology, psychotropic medications used, and a variety of assessment and intervention techniques. Of particular importance is an understanding and appreciation of the complex nature of childhood psychosis and the interactions among various problem areas. Assessment and interventions likely will be multifaceted and require considerable skill to develop and implement. Optimal interventions for these children should follow a problem-solving process, such as that described above.

In closing, an essential point to remember is that children with psychosis will experience problems throughout their lives. Cullinan et al. (1983) have summarized some research findings on children with psychosis that are pertinent to consider:

1. No treatment — psychodynamic, psychoeducational, behavioral, drug, megavitamin, or any other — can make psychotic children normal.

2. Except for drug therapy, which is rarely used alone, all interventions require great effort over a very long period of time.

3. Psychotic children have the best chance for meaningful improvement in *educational* programs — ones in which the therapists, parents, school teachers, and other interventionists teach needed skills and eliminate nonfunctional behaviors that interfere with the child's learning and social acceptability (pp. 242–243).

Progress can be expected to be slow, uneven, and long-term, and expecting the child to achieve "normalcy" is unrealistic. Nevertheless, with collaborative efforts by parents and professionals, some academic and social gains should be realized over time.

ANNOTATED BIBLIOGRAPHY

Achenbach, T. M. (1982). *Developmental psychopathology* (2nd ed.). New York: Wiley.
This book gives a thorough description of the concepts of developmental psychopathology, and discusses individual disorders from a developmental perspective. Included are chapters on intervention, etiology, assessment, and classification of disorders. This book is a valuable resource for psychologists who wish to understand and apply principles of developmental psychopathology.

Clarizio, H. F., & McCoy, G. F. (1983). *Behavior disorders in children* (3rd ed.). New York: Harper and Row.
This book provides a comprehensive treatment of childhood disorders and includes good information about the impact of disorders on school performance. Each chapter describes well a specific disorder, and includes discussion of educational issues and possible methods for intervention. The book also is likely to be helpful in differential diagnosis situations, and would be a valuable reference for the practitioner.

Stoner, G., Shinn, M. R., & Walker, H. M. (Eds.). (1991). *Interventions for achievement and behavior problems.* Washington, DC: National Association of School Psychologists.
This volume of near[illegible] pages describes a wide range of school-based interventions for academic and social/emotional/behavioral problems for students of all ages. The book is divided into helpful sections: Evaluation Issues, General Intervention Strategies, Interventions for Target Areas by Level, Interventions for Specific Problems, and Training Intervention Oriented School Psychologists. The book is especially useful for working with children with psychosis, who present a variety of problems that need a multifaceted approach.

Thomas, A., & Grimes, J. (Eds.). (1990). *Best practices in school psychology–II.* Washington, DC: National Association of School Psychologists.

Like the NASP's *Interventions for achievement and behavior problems* described above, this book covers a wide array of topics pertinent to student problems. The topics are very specific and cover a range of conceptual and practical issues, many of which will apply directly to childhood psychosis and can be readily adapted. The book will be a valuable resource regarding best practice in many areas related to childhood psychosis.

Best Practices in Working with Culturally Different Families

Dawn P. Flanagan
St. John's University

> *Culture is akin to being the observer, through the one-way mirror; everything we see is from our own perspective. It is only when we join the observed on the other side that it is possible to see ourselves and others clearly — but getting to the other side of the glass presents many challenges.*
>
> — Eleanor W. Lynch (1992, p. 35)

OVERVIEW

The United States is becoming an increasingly diverse nation. The number of children from nonwhite and non-Anglo white families is growing. This growth is expected to continue despite the fact that the percentage of children that make up the total U.S. population is decreasing (Counting the Children, 1989). It is estimated that by the year 2000, 38% of the U.S. population under the age of 18 will be non-Anglo whites and nonwhites (Research and Policy Committee of the Committee for Economic Development, 1987) and by the year 2030, the number of Latino children, African American children, and children of other races, will increase by 5.5, 2.6, and 1.5 million, respectively, while the number of white, non-Latino children will decrease by 6.2 million from the 1985 figure (Children's Defense Fund, 1989). These dramatic changes in the ethnic composition of the United States can be attributed to increasing birth rates among non-Anglo women and decreasing birth rates among the resident Anglo population; increasing numbers of non-Anglo women of childbearing age; increased immigration of non-Europeans; and increased longevity among ethnically diverse populations (Hanson, Lynch, & Wayman, 1990; Huang & Gibbs, 1992).

In addition to these demographic changes, today's families are also undergoing significant changes. First, the percentage of traditional, nuclear families in the United States is decreasing while the percentage of nontraditional families, including single parents, step parents, grandparents, adoptives, foster parents, and same-sex parents, is increasing (Copeland & White, 1991; Masnick & Bane, 1980). Second, the percentage of young women having children is on the rise as well as the percentage of women electing to marry and bear children at later ages (Levitan, Belous, & Gallo, 1988). Third, family size has decreased in the past few decades among the U.S. Anglo population, while the average number of births per woman in other ethnic/cultural groups has increased (Hanson et al., 1990). Family size is also influenced by the number of individuals who reside in the same household but are not part of the nuclear family (e.g., grandparents). Many individuals who recently immigrated to the United States, for example, reside in large, extended families for cultural and economic reasons (Wayman, Lynch, & Hanson, 1990). Finally, although several sociohistorical events have had an effect on families in recent years, "the disproportionate decrease in the standard of living of many children and families in the United States is perhaps the single most significant sociohistorical change affecting families today" (Hanson & Lynch, 1992, p. 291). For example, in 1989, 41% of poor children resided in a household with an income below half of the poverty line (i.e., an income of $412 per month) (Children's Defense Fund, 1991, cited in Hanson & Lynch, 1992).

These powerful demographic and familial changes have culminated in a multitude of cultural patterns and characteristics, languages, values, beliefs, attitudes, and behaviors. As a result of the increasing ethnic/cultural diversity of the United States, the number of non-Anglo children and their families who require early intervention services is on the rise. Moreover, the recent enactment of Public Law 99-457 (Individuals With Disabilities Education Act, 1991) has served to increase the extent to which school psychologists form partnerships with families. Ideally, families requiring early intervention services should be matched with at least one service provider whose language and experience are similar to that of the family in order to ensure caring, sensitivity, and responsive service delivery. Unfortunately, the provision of services to culturally different families is not likely to include this ideal component in the near future.

Training programs that prepare professionals to work with children with disabilities and their families do not include large numbers of students from differing ethnic, cultural, and linguistic groups (Hanson, 1992). Although the number of non-Anglo children attending early intervention programs is increasing, by the year 2000 the persons providing services to these children and their families will be predominantly Anglo-whites (Hanson, 1990, 1992). This mismatch between families and service providers can result in "cultural clashes." That is, when the values and beliefs of culturally diverse families differ from the U.S. mainstream's values and beliefs held by service providers, conflict and/or miscommunication will likely ensue, thereby diminishing the effectiveness of service delivery. Thus, recruiting students from diverse backgrounds and expanding university curricula to include an emphasis on multicultural education (Banks, 1993; Hanson, 1992) must begin in earnest and remain a top priority well into the twenty-first century. In the meantime, school psychologists and other service providers must strive to develop a respect for the values of other cultures so that they can identify more effectively the concerns, priorities, needs, strengths, and resources of the families with whom they work (Hanson, 1992).

At present, many school psychologists are faced with the challenge of providing services to children of ethnically diverse backgrounds and to their families in the absence of prior training in multicultural education, in general, and prior experience in working with culturally different families, in particular. As a result of their lack of training and experience, many school psychologists are ill-prepared and therefore, reluctant to work with families whose cultural backgrounds differ from their own. The purpose of this chapter is to provide school psychologists with a foundation from which to build or enhance their skills in providing services to culturally different families and from which to begin exploring, understanding, and appreciating diversity. Specifically, this chapter will provide useful terms that need to be understood by school psychologists prior to working with culturally different families so that they can clearly delineate the dimensions along which difference is defined. In addition, this chapter will present a culture-oriented perspective of family systems and discuss how school psychologists can begin to develop cross-cultural awareness and competence. This chapter will conclude with a summary of guidelines for gathering culturally relevant data that can be used by school psychologists to learn more about the practices and functions of the families with whom they work.

BASIC CONSIDERATIONS

The phrase *culturally different* is used in this chapter to describe families who come from cultural backgrounds that differ from the school psychologist's, which in many instances means that they differ from mainstream U.S. culture. However, school psychologists should guard against treating "culturally different families" as a uniform group. They are *similar* only in that their respective cultural backgrounds differ from that of the professional. There are a number of salient dimensions along which families differ including culture, race, ethnicity, socioeconomic status (SES), and level of acculturation. School psychologists who assess a family's status along each of these dimensions will be more sensitive to the specific ways in which the family's priorities, strengths, resources, and needs differ from their own. Often, differences among families categorized as culturally different become clouded by the psychologist's tendency to view difference as unidimensional. Adopting a multidimensional way of thinking about difference will circumvent our tendency to generalize across a variety of cultures. The following definitions are offered to provide school psychologists with an understanding of the most salient dimensions along which families differ.

Terminology

Culture. There is often confusion over the connotative meaning of the term *culture* (Frisby, 1992a). According to Frisby (1992a), there are approximately six connotative meanings associated with the term in contemporary society. One meaning is the "characteristic patterns of living, customs, traditions, values, and attitudes that are associated with broad differences in intercontinental habitation or a society's level of technological sophistication" (Frisby, 1992a, p. 533). Thus, an industrialized society characterized by ongoing technological advancement is implied in the term *modern* as opposed to *primitive* culture. Another definition of culture refers to the unique contributions of the members of a given ethnic/racial group or ancestral homeland including humanitarian, scientific, or artistic accomplishments. Many U.S. schools, for example, have revised their social studies curriculums to include sociohistorical events that highlight the significant contributions of African civilizations or African American leaders in an attempt to provide all individuals with an educational foundation in "black culture" (Frisby, 1992a; Huang & Gibbs, 1992).

A third concept of culture has been labeled "race consciousness" by Hall and Allen (1989); it refers to behaviors, attitudes, and beliefs that serve to advance interest in and promote identification with one's race regardless of differing levels of education, social class status, or area of residence (Frisby, 1992b; McGhee, 1983). Sensitivity to and awareness of racial prejudice or discrimination is a component of racial consciousness. A fourth meaning of culture reflects the values, beliefs, and customs that are inherent in the environments in which a person receives information about society. Individuals who recently immigrated to the United States, for example, may find the "culture" of their family to be very different from the "culture" of U.S. schools. The remaining two concepts of culture are more superficial: Individuals may be regarded as "culturally different" because of their adherence to particular styles of dress, religious worship, culinary practices, and so on, or as a result of outer appearances alone (e.g., skin pigmentation) (Frisby, 1992a; McGoldrick, Pearce, & Giordano, 1982; Stewart & Bennett, 1991).

From the above definitions, it is evident that much information is conveyed through the casual use of the term "culture." Therefore, culture must not be viewed as "a rigidly prescribed set of behaviors or characteristics, but rather a framework through which actions are filtered or checked as individuals go about daily life" (Hanson, 1992, p. 3). Although individuals of the same cultural background share certain tendencies, they do not necessarily behave in the same way, since behavior is also influenced by such factors as gender, age, socioeconomic status, area of residence, and level of education (Hanson, 1992). The degree to which individuals follow a prescribed assemblage of cultural patterns varies considerably; there exists a vast continuum reflecting the extent to which individuals identify with a particular cultural group or groups (Frisby, 1992a; Gopaul-McNicol, 1992; Hanson, 1992). Thus, school psychologists must appreciate all the nuances inherent in the notion of culture, since their precision regarding its meaning directly impacts on how effectively they can communicate with diverse families.

Ethnicity and race. Related to culture but narrower in scope is the concept of *ethnic group*. Banks and McGee Banks (1993) define ethnic group as "a microcultural group or collectivity that shares a common history and culture, common values, behaviors, and other characteristics that cause members of the group to have a shared identity" (p. 357). It is important to note here that although the terms *ethnicity* and *race* are often used interchangeably, they are separate concepts. Race is a biological concept that refers to phenotypically distinct groups. Thus, cultural traits are the main attributes of an ethnic group while biological traits determine race (Banks & McGee Banks, 1993).

Minority. Another important concept to understand is minority group. The term *minority* may be used to refer to a small group of privileged individuals. However, it is more typically used to refer to a proportionately smaller group, in contrast to the majority group in a society, that is disadvantaged (due to such factors as limited opportunity for educational and/or economic advancement) and treated unfavorably by the majority group. Groups that differ from the majority group in race or ethnicity often are treated unfavorably by the majority group and as a result acquire an underprivileged minority status. Moreover, when a minority group is considered underprivileged because of unfavorable treatment or other variables related to deprivation and discrimination, the psychological well-being of the group's family life will likely be affected adversely (Tseng & Hall, 1991).

Socioeconomic status. An additional central concept to have knowledge of is *socioeconomic status* (SES), since it defines an individual's world. Membership in a particular social class has a profound impact on essentially every variable that influences an individual's physical and psychological growth and development. These variables range from educational attainment, occupational aspirations, and lifestyles to selection of friends, activities, and social roles. Thus, as social class varies, so do the range of opportunities, the kind of choices, and the degree of challenges that are available to individuals and their families (Huang & Gibbs, 1992).

Social class and its interrelationship with ethnicity and race complicate further the plight of culturally diverse families living in the United States. Essentially, being a member of white, Anglo-Saxon, middle-class families is reflective of high status whereas being a member of non-Anglo, or non-white, working-class families is reflective of low status. This means that "youth in many Asian, Black, Hispanic, and Indian families are triply stigmatized in American society because they differ from the ideal norm in three major respects: They are non-white by race (except for Spanish-speaking whites), non-Anglo-Saxon by ethnicity, and predominantly non-middle-class by socioeconomic status" (Huang & Gibbs, 1992, p. 85). Thus, the school psychologist's familiarity with the separate definitions of culture, ethnicity, race, minority group, and SES is not enough to ensure sensitivity and effective communication when working with culturally different families. School psychologists must also understand that the connotations inherent in these concepts are often inextricable and subsequently come to appreciate the interrelationships among them.

Acculturation. A final useful term that is necessary to understand before providing services to culturally different families is *acculturation*. Acculturation may be defined as the set of circumstances that result when two cultures experience, first hand, the subsequent alterations in the fundamental sociocultural system of one or both groups (Redfield, Linton, & Herskovits, 1936). When migrant families leave their homeland and move to new locations, they may find that the sociocultural system that obtains in their new place of residence differs significantly from the one they left behind. As a result, these families may feel pressure to conform to different ways of thinking that are characteristic of their new environment. In addition, they may have to adjust to a new way of life regarding occupation, financial resources, and social network (Tseng & Hsu, 1991).

This adjustment process is influenced by several factors, including the migrants' reason for migration, their occupational/educational attainment, the climate of reception in the new host society, and the degree of compatibility between the cultures of the migrants and the host society. Further complicating the adjustment process is the degree and pace of conformity to a new cultural system. For example, often young children are more adept at learning a new language and more amenable to assuming new social roles than their middle-aged parents. This differing pace of adjustment may create tension and disharmony within the family and disrupt the family hierarchy. That is, as a result of the child's more rapid pace of adjustment to a new cultural system, the roles and status of the parents and child may reverse, particularly when the child is forced to assume the role of emissary for the parents in certain social contexts (Huang, 1989; Huang & Gibbs, 1992; Tseng & Hsu, 1991).

The degree to which an individual acculturates influences her or his attitudes, values, and beliefs. Five stages or levels of acculturation have been proposed by Atkinson, Morten, and Sue (1989) and presented in Nuttall, De Leon, and Valle (1990) in an attempt to explain how minority individuals react to the dominant culture. Briefly, at the first level (Conformity), minority individuals do not like themselves or those who share membership in the same minority group; they admire members of the dominant group. The second level of acculturation (Dissonance) is seen as a time of conflict in which the migrant's preference for the views of the majority culture, vis a vis their previous views, waxes and wanes. At the third level (Resistance and Immersion), minority individuals have come to appreciate themselves and their affiliation with a minority group but have developed a dislike for the majority group. Also, at this level, empathic feelings for other minority groups are expressed; however, they are in direct conflict with feelings of ethnocentrism. At level 4 (Introspection), individuals begin to explore the grounds on which they can justify liking themselves and members of their minority group. Finally, at level 5 (Synergetic Articulation and Awareness), individuals come to appreciate themselves, their own group, other ethnic minority groups, and particular aspects of the majority culture.

Knowing a family's current level of acculturation provides an additional perspective from which the school psychologist can develop plans for service delivery. For example, a family that is functioning at level 1 or level 5 is likely to respond positively to interactions with service providers of the dominant culture, whereas a family functioning at level 3 will likely respond negatively or avoid such interactions (Nuttall et al., 1990). Also, it is important to understand that highly acculturated minority individuals may have more in common with members of the dominant culture than with members of their own group. Thus, a third generation Vietnamese family may have more in common with a white middle-class family than with a Vietnamese immigrant (Huang & Gibbs, 1992). Given the varying degrees of acculturation that may be experienced by ethnic minority individuals, and its resultant impact on the attitudes, values, and beliefs held by minority families, the importance of knowing the level that has been reached by the family or family members prior to service delivery cannot be overemphasized.

Family Systems

In addition to mastering the various concepts presented above, a consideration and basic understanding of the ways in which family systems function is also necessary to enable the school psychologist to work more effectively with families of various cultural backgrounds. There are numerous patterns of family systems that exist worldwide, many of which are influenced by external political, economic, and sociocultural factors as opposed to internal emotional and psychological (family) factors. Moreover, different family systems have emerged in response to different social contexts as well as to solutions to problems that reflect the psychological milieu in which they live, rather than by a predetermined evolutional course or by chance (Tseng & Hsu, 1991). It is beyond the scope of this chapter to examine all the cultural aspects of family systems, family development, and family function. Therefore, only a brief cross-cultural perspective of how family systems function will be presented here. (For a more comprehensive examination of culture and family systems, see Tseng & Hsu, 1991.)

The term *family* is defined by Tseng and Hsu (1991) as "the basic sociocultural unit . . . the nest for the growth of an individual, the resource for social support, and the institution through which culture is transmitted" (p. 1). Although the term takes on a variety of concepts and meanings across cultures, what is clear is that this social unit plays a significant role in cultivating the growth, development, and psychological well-being of its children (Lewis, Beavers, Gossett, & Phillips, 1976). When a family has a child with a disability or other at-risk condition, it is likely that they will come into contact with a school psychologist or other service provider. The family may seek out or welcome services from these professionals or they may have reservations regarding the need and desirability of services (Hanson, 1992). The perceived need for services may be influenced by a number of variables including the emotional state of the family at the time of referral; the attitudes, values, and belief systems of the family; the match between the culture of the family and the culture of the service provider; the family's level of acculturation; and the family's social support system, to name a few. School psychologists can provide culturally appropriate services to families of different cultural backgrounds only if they understand the fundamental cultural aspects of family systems and function. In order to begin to understand and distinguish between differing family patterns, it is helpful to examine the most salient parameters of family systems such as marriage forms, postmarital residence, kinship system, and family structure (Tseng & Hsu, 1991).

Marriage. Each society has its own rules regarding marriage. In the United States as well as in most contemporary developed societies, *monogamy* is the norm. However, in more than 80% of the societies worldwide (based on those listed in the *Ethnographic Atlas*, Murdock, 1967), monogamy with *polygyny* (i.e., having more than one wife) or only polygyny is preferred (Hoebel, 1972). In many societies, polygyny can increase a man's wealth, his social position, and his affiliations with various groups, especially when his wives are economically important. Although considerably less prevalent, *polyandry* (having more than one husband) is preferred among many tribes in India (e.g., Tibetans; Hoebel, 1972); in these societies, property is scarce and brothers often will marry a common wife to circumvent division of assets. Thus, although not common in the United States, polygyny and polyandry serve significant political and economic functions in many societies around the world (Tseng & Hsu, 1991).

Residence. Different patterns of postmarital residence are also evident across cultures. These patterns of residence are usually dictated by ecological factors. For example, when the primary means of support or livelihood rests with the male, the married couple will likely live near the husband's family. Conversely, when the woman plays a prominent role in subsistence, as is seen in horticultural societies where cooperation among women is important, then the couple will benefit from living near the wife's family. Finally, in societies that are characterized by a high degree of mobility and value independence within the nuclear family, such as the United States and other industrialized and urbanized societies, a married couple will typically live apart from the families of both spouses. Thus, the role(s) assumed by each spouse, the power distribution within the family, and the configuration of kinship relationships are impacted by the choice of residence following marriage (Stewart & Bennett, 1991; Tseng & Hsu, 1991).

Kinship. Another parameter of family systems that is useful to examine from a cross-cultural perspective is the kinship system. A ***kinship system***, according to Tseng and Hsu (1991), is "the totality of relationships based on blood and marriage that links individuals, through a web of rights and obligations, to the kinds of groups formed in a society on the basis of kinship" (p. 9–10).

The perpetuation of any society is dependent on the functions of kinship. In the majority of societies, individuals are associated with sets of kin following certain rules of descent. For example, the most common type of descent system (i.e., *patrilineal*) associates individuals with both male and female kin through the males. Each generation of children belong to the father's kin group and carry his family name. Furthermore, an individual's lineage is traced through the grandfather, father, son, and grandson line. The far fewer societies that are characterized by a *matrilineal* descent system reflect the same rules of descent as the patrilineal system except that descent association is transferred through females (Ember & Ember, 1973; Tseng & Hsu, 1991).

In a third type of descent system, *ambilineal*, individuals are associated with both male and female kin through either males or females, resulting in a society in which some children belong to the father's kin group and some to the mother's kin group (Ember & Ember, 1973). These different types of descent groups appear to reflect the type of subsistence base that predominates in the associated societies (Tseng & Hsu, 1991). Thus, a subsistence base characterized by pastoralism is associated with a patrilineal descent system, one defined by developed agriculture with a matrilineal system, and one defined by hunting and gathering with an ambilineal system (Schneider & Gough, 1961).

Structure of the family. Related to the different descent systems that exist across cultures are the various configurations of family that assemble on the basis of kinship. For example, the *nuclear* family, composed of parents and their unmarried children, is the most frequently occurring family structure in modern industrialized and in hunter/gatherer societies (i.e., in societies that necessitate substantial mobility). However, in cultivating societies, *extended* families are widespread, primarily for economic reasons; since extended families may include a spouse's married siblings and their children, a greater number of workers are available through this type of kinship network than through nuclear families (Tseng & Hsu, 1991). The presumably "ideal" nuclear family actually exists in a very small percentage of societies worldwide (Nanda, 1980). Furthermore, although the nuclear family currently predominates in the United States, an increasing number of extended family systems are forming due to the impact that changing demographcis are having on U.S. society.

These changing demographics, for example, have resulted in a prevalence of extended families among Asian Americans, African Americans, and Native

Americans. In addition, the importance of the family and extended kinship bonds are securely established in the traditional values of Latino families who reside in the United States (Huang & Gibbs, 1992). It is important to note here that the methods by which societies categorize kin may or may not be dependent on biological ties (Cunningham, Cunningham, & O'Connell, 1986; Harry, 1992; Nanda, 1980). For example, strong kinship bonds among many African American families may result in a multitude of linkages between domestic units that include blood relatives and "fictive kin" (Huang & Gibbs, 1992). Through these coherent networks of extended families, mutual emotional and economic support is provided. Thus, a variety of individuals including friends, neighbors, siblings, and grandparents may participate in raising or caring for any one African American child, especially in times of economic stress or illness (Huang & Gibbs, 1992; Stack, 1975).

Another important element to consider when examining the structure of the family is which family member is given the power to make important decisions. In the United States, for example, an egalitarian family in which power and authority are distributed equally is preferred and practiced commonly. Conversely, in societies marked by patrilineal and matrilineal descent systems, the individuals who exercise authority in kin groups are male. In a patrilineal system, authority is typically delegated to the father or grandfather and in a matrilineal system, to the woman's brother(s). Although many decisions may be made jointly by both husband and wife in private, irrespective of the rules inherent in particular descent systems, it is important to recognize and respect the cultural patterns that are emphasized in public (Tseng & Hsu, 1991). For instance, in many Asian American families, "fathers are often the figurative heads . . . especially when dealing with the public, whereas the mother may actually be the driving force in the family and the decision maker behind the scene" (Huang & Gibbs, 1992, pp. 86–87). Unless professionals understand and defer to these cultural patterns in their interactions with families, they may be perceived as disrespectful and the effectiveness of service delivery will be hampered.

In summary, there are many different aspects of the family that need to be considered by the school psychologist from a cross-cultural perspective. An understanding of the economic, political, ecological, and social conditions that play a role in shaping a family's unique cultural patterns will aid in providing an individualized approach to service delivery, where intervention is tailored to the family's needs, as well as provide a foundation from which to help the family understand U.S. culture. Only through knowledge and awareness can school psychologists recognize the strengths of different family structures and respond sensitively and effectively to families whose cultural practices differ from their own.

BEST PRACTICES IN WORKING WITH CULTURALLY DIFFERENT FAMILIES

Developing Cultural Awareness and Competence

Until recently, little attention has been given to developing cross-cultural competence and to understanding the effects that cultural differences have on interpersonal relations. Achieving cross-cultural competence is an effortful process that requires individuals to take risks, lower their defenses, and set aside their own beliefs in an attempt to adopt another's viewpoint. For individuals who are just beginning to develop cross-cultural competence, it is likely that some encounters with culturally different families will be uncomfortable, especially when they require that we change our typical ways of thinking and behaving.

> For most people, including Americans, the distinguishing mark of cross-cultural interaction is the disappearance of the familiar guideposts that allow them to act without thinking in their own culture. Routine matters become problems that require planning or conscious decisions. They may not know when to shake hands, nod their heads, ask a question, express an opinion, or maintain silence. They may have to question the effectiveness of their techniques for giving advice and may need to search for proper channels of communication. (Stewart & Bennett, 1991, pp. 2–3

The rewards of developing effective skills for working with families whose cultures differ from our own, however, far outweigh the feelings of unfamiliarity and uncertainty that may be associated with initial cross-cultural interactions. That is, as we become more knowledgeable about other cultures and the nuances of our own culture, we will be better able to help families bridge the gap between two distinct cultures and be more effectual in our interpersonal communications (Lynch, 1992).

Developing cross-cultural competence does not happen overnight and we cannot expect to know everything there is to know about every culture. However, through an open mind and a willingness to implement new ideas, we can acquire specific strategies that will enable us to work effectively and sensitively with culturally different families, as well as enable families to feel comfortable about their interactions with service providers. Strategies that have been shown to be effective in working with culturally diverse families are interspersed throughout the psychology and special education literature (e.g., Allen & Boykin, 1992; Chan, 1990; Hanson et al., 1990; Harry, 1992; Lynch, 1992). The purpose of this section of the chapter is to present those strategies that will be most useful for school psychologists who are just beginning to develop cross-cultural competence.

Awareness. Cultural self-awareness is the first step to developing cross-cultural competence (Chan, 1990; Hanson et al., 1990; Harry, 1992; Lynch, 1992). In order for school psychologists and other service providers to completely comprehend and acknowledge the diversity that exists across cultures and, more specifically, among the families they serve, they must understand and appreciate their own culture. A beginning step in this process involves exploring one's own heritage, including place of origin, time of and reason for migration, and location of the family's first settlement in the United States. This may be accomplished through talking with the eldest family members or through document searches in county court houses, churches, or libraries. The goal here is to gain an appreciation of how one's own values, beliefs, attitudes, and customs have been molded by culture. In this way, values and beliefs that have been assumed to be universal can be viewed separately from those that are culture-specific (Chan, 1990; Lynch, 1992).

In addition to becoming knowledgeable about one's own cultural heritage, school psychologists should analyze the values and beliefs that are characteristic of mainstream U.S. culture. American values emphasize individualism, independence, autonomy, interpersonal competition, mastery, equality, punctuality, materialism, progress, and a future orientation. In addition, Americans prefer interactions that are informal rather than formal, have a high regard for achievement, and take pride in direct and assertive interactional styles (Althen, 1988; Pinderhughes, 1982). School psychologists who understand the extent to which they identify with each of these values will be in a better position to determine how the values that they adhere to most strongly affect their practice (Stewart & Bennett, 1991; Lynch, 1992).

School psychologists who value independence and autonomy in young children, for example, and who believe in promoting the attainment of developmental milestones and correcting slight deviations from the norm, may have difficulty understanding why some Native American and Latino parents have a relaxed attitude toward their children's achievement of self-reliance (Huang & Gibbs, 1992). School psychologists who value individual achievement and interpersonal competition may have difficulty working with families who come from a cultural background that values interpersonal affiliation, cooperation, and reciprocity (e.g., Latino families). School psychologists who believe that the source of a child's disability lies in physical phenomena rather than spiritual will likely experience discord with parents who are committed to spiritual rather than medical treatments (e.g., some Southeast Asian groups) (Chan, 1986; Harry, 1992). Determining the extent to which one's own cultural values differ from those of other cultures, as well as the extent to which adhering to these values affects the intervention and treatment of children with disabilities and their families, will provide school psychologists with a more realistic perspective regarding their ability to engage in unbiased service. Thus, cultural self-awareness provides the foundation from which to discover the intricacies of other cultures and build effective relationships with culturally different families.

Knowledge and awareness of specific cultures. Once school psychologists have explored their own roots and examined the extent to which their cultural values and beliefs influence the ways in which they practice, they are ready to move into the second phase of developing cross-cultural competence — that is, learning about other cultures (Cross, 1981; Hanson et al., 1990; Lynch, 1992). This discussion is presented with two caveats. First, generalizations regarding the values, beliefs, or characteristics of a particular culture may obscure important differences within the cultural group. Second, the characteristics that determine a family's values, beliefs, and behaviors are numerous. In addition to culture, socioeconomic status, level of acculturation, level of education, reason for immigration, and geographic location are but a few of the important variables that influence and shape the values, beliefs, and behaviors embraced by culturally different families (Hanson, 1992; Harry, 1992; Lynch, 1992; Tseng & Hsu, 1991).

To illustrate, Puerto Rican families value spirituality and humanism over commercialism. However, these values are more typical of the lower-SES classes; Puerto Ricans who belong to middle and upper classes value possessions as highly symbolic of personal worth (Garcia-Preto, 1982). Thus, although an author's portrayal of a culture-specific paradigm necessitates generalizations, school psychologists should be cautious in making them and limit their generalizations from any given group to similar groups who have experienced similar circumstances.

Generalizations notwithstanding, specific information about a given culture aids in understanding the values, beliefs, and behaviors that are expressed in cross-cultural interactions. According to Lynch (1992) some of the most effective ways of gathering culture-specific information include the following: (a) acquiring knowledge about another culture through reading and studying, (b) interacting with individuals from another culture who can serve as guides or mediators, (c) engaging in the lifeways of another culture (e.g., through community activities or religious worship), and (d) learning the language of another culture.

The most efficient way for school psychologists to learn about the specific cultures of the families with whom they work is to read. In searching for reading materials, it is important to keep in mind that critical insights and viewpoints regarding any given culture may be communicated by authors who are from that culture. Therefore, it may be helpful to review several sources in order to appreciate and understand differing viewpoints regarding cultural values and cross-cultural interactions (Lynch, 1992). Viewing culture from the perspectives of many authors helps to orient school psychologists to a particular culture and increase their awareness regarding cultural differences. However, specific information pertaining to family patterns and practices is necessary to ensure that school psychologists appropriately match interventions to a family's unique lifestyle and needs.

Information related to a family's childrearing practices, family structure and function, perceptions of disability and its source, perceptions of interventions, and willingness or desire to change is useful for developing intervention plans that incorporate the family's values, beliefs, and ways of life (Hanson & Lynch, 1992; Hanson et al., 1990; Lynch, 1992). Suggesting that a behavior modification program be implemented by the parents of a young Native American child who is noncompliant may be perceived by the family as inappropriate and may even humiliate some family members. This is because, in many Native American tribes, information about a child's misbehavior is passed from the mother to an extended family member who has been appointed as the individual responsible for cultivating the child's character development; this direct communication serves to protect the parent–child bond as well as extended family connections (Huang & Gibbs, 1992).

In this example, the interventionist lacked adequate information concerning the family's childrearing practices, their patterns of communication, and the value that they place on the extended family system; therefore, a behavior program was selected that was incongruent with the family's values. The interventionist would have had a better chance of successfully implementing the behavior program if he or she had included influential family members, other than the parents, in its development. Thus, the more culture-specific information school psychologists obtain, the more sensitive they will be to different family systems and functions and the better equipped they will be to devise intervention plans that are congruent with the family's values, beliefs, traditional practices, and lifeways.

Although reading about a specific culture provides school psychologists with a wealth of information that will lead to a greater respect for and understanding of the values and beliefs that culturally different families embrace, it is not sufficient. Other enriching experiences are necessary to heighten one's awareness and understanding of different cultures. Interacting with and observing members of another culture, participating in various community activities of diverse cultures, and learning the language of another culture all provide additional opportunities to study different cultures and strengthen one's commitment to developing cross-cultural competence (Hanson & Lynch, 1992; Hanson et al., 1990; Lynch, 1992).

The extent of one's commitment to developing cross-cultural competence, however, will likely be a direct reflection of the nature and diversity of the populations served. School psychologists who work *occasionally* with Muslim or Vietnamese children and their families, for example, will likely derive much of their information about these cultures through reading materials. On the other hand, school psychologists who work in areas encompassing large Asian American, African American, and/or Latino communities, may spend more time in open discussion and interpersonal sharing with members of these communities, as well as participating in holiday celebrations and other community activities, in an effort to increase their understanding of these specific cultures. Finally, school psychologists who work *primarily* with children and families whose cultural background differs from their own may choose to learn the language of that culture, since "much of what is described as culture is reflected in language" (Lynch, 1992, p. 41). The number of bilingual school psychology programs that have emerged within the last decade demonstrates the importance of language in understanding other cultures as well as a strong commitment to developing cross-cultural competence.

Communication. School psychologists who speak the same language as the families they serve may experience more effective interpersonal interactions than those who do not. However, an understanding of how different cultures transmit information *nonverbally* is also necessary for effective communication and will increase one's competence in cross-cultural interactions.

When working with culturally different families, it is important for school psychologists to understand that the amount of information that is communicated explicitly through words versus the amount of information that is communicated through contextual cues varies considerably from one culture to the next (Hall, 1976). In high-context cultures, such as Asian, Native American, African American, and Latino, meaning is derived typically through shared experience, history, and implicit messages. Conversely, in low-context cultures, such as the British, Swiss, German, and Scandinavian cultures, and those of their U.S. descendants, meaning is derived from direct, precise, and logical verbal interchanges. Misunderstandings between school psychologists and families may arise when the level of context that each party uses to communicate with one another differs. Individuals from high-context cultures, for example, may perceive specific verbal directions, detailed examples, and extensive elaboration as insensitive and mechanistic, whereas individuals from low-context cultures may feel uncomfortable with silence, obscure phrases, or unfamiliar gesturing. Thus, it is the school psychologist's responsibility to observe family communication patterns or consult with colleagues or other members of the family's culture to determine what level of reliance on context the family uses to communicate. This information will enable the school psychologists to adjust their style of communication to match those of the families with whom they work (Hanson et al., 1990; Lynch, 1992).

In addition to learning about culturally different communication patterns, school psychologists should become familiar with the meanings and uses of specific nonverbal behaviors across cultures. For example, prolonged eye contact between individuals in Latino cultures is considered disrespectful and eye contact between two strangers in some Asian cultures is regarded as shameful (Randall-David, 1989, cited in Lynch, 1992). Other nonverbal behaviors, such as specific facial expressions, amount of distance considered to be comfortable between two individuals engaged in conversation, type of physical contact permitted (e.g., a hand shake, hug, slap on the back), and gestural language, are influenced greatly by culture and differ as a function of age, gender, religion, and personal preference. Although the school psychologist cannot learn all the culturally appropriate ways of communicating and behaving, by acknowledging the most salient patterns of nonverbal communication within a given culture, they can interact and behave in ways that are respectable (Lynch, 1992). School psychologists interested in learning more about nonverbal communication across cultures may wish to begin by reading Lynch and Hanson (1992; see annotated bibliography).

In our zeal to learn as much as we can about a particular culture, gathering bits and pieces of information about unique family patterns, values, beliefs, and so forth, before an initial parent conference, we must not forget the most integral component of effective communication — the ability to view the world from the family's perspective. What is the family thinking, feeling, experiencing? The only way we are going to intervene effectively with families is to understand and respect their viewpoint, even when it is at odds with our own values and typical approaches to service delivery. Our interventions will be successful only in so far as they are culturally relevant to families.

Guidelines for Gathering Culturally Relevant Data

Understanding the cultural aspects of family systems and function will enable school psychologists to match intervention with the needs and lifestyles of families from diverse cultural backgrounds effectively. Several useful guidelines and suggestions have been offered in an attempt to assist service providers in gathering culturally relevant information from family members (Boyd-Franklin, 1989; Gopaul-McNicol, 1993; Hanson et al., 1990; Lynch, 1992; Lynch & Hanson, 1992; Ruiz & Padilla, 1979; Tseng & Hsu, 1991; Wayman et al., 1990). Although some of these guidelines were designed to be used with specific cultural groups (e.g., West Indians; Gopaul-McNicol, 1993) and others were designed to be used in early childhood settings (e.g., Wayman et al., 1990), they have direct relevance for *all* cultural groups and can be altered easily to fit families whose children are older and therefore likely to be seen by school psychologists rather than early interventionists. The following guidelines have been selected from the above sources and are useful for school psychologists to consider when structuring their interactions with culturally different families.

1. *Establish rapport and build trust.* School psychologists should attempt to put the family at ease. This requires patience, effective listening skills, and a willingness to take the time necessary to establish mutual goals. For example, Ruiz and Padilla (1979) suggest that when counseling Latinos, it is important to realize that in Latin American cultures there is a preference for personal contact and individualized attention when dealing with social institutions. Latino clients will be more comfortable and receptive to service providers who work to establish a personal relationship that is consistent with Latin American cultural characteristics. In an attempt to assist service providers in establishing this type of relationship, these authors offer the following suggestions. Greet the client on arrival, even though this may require interrupting briefly other activities. Extend your hand and introduce yourself, using your first name rather than your formal title. Finally, allow time for so-called "small talk." Moreover, continuing these informal interchanges at the beginning of subsequent sessions will help to maintain rapport.

When working with families who have recently immigrated to the United States, it may also be necessary to explain how other systems operate (e.g., educational, legal, political). To determine whether the provision of this information is necessary, school psychologists can assess (by an interview) the family's level of acculturation and understanding of relevant social institutions. There are also other tools available to assess a family's level of acculturation. For example, the West Indian Comprehensive Assessment Battery (WICAB) (Gopaul-McNicol, 1993) is designed to determine the extent to which a West Indian immigrant has assimilated into U.S. society.

2. *Identify the presenting problem.* School psychologists should listen to the family's perception of the problem and attempt to understand it from their perspective. It is also necessary to determine the family's past efforts to resolve the problem and to elicit their present understanding of treatment goals. Once these issues have been clarified, the school psycholo-

gist will be in a position to negotiate intervention strategies.

The following example, provided by Boyd-Franklin (1989), highlights the importance of taking the time to learn the client's presenting concerns. In this case, a 40-year-old African American woman began to cancel therapy appointments for herself and a 7-year-old boy, Carl, whom she had been caring for since he was 1-year-old. The client had stopped coming to appointments because she perceived the therapist as an extension of the child welfare agency, which was pressuring her to adopt her "son" or give him up so that another family could adopt him. This mother's fear that her child was going to be removed is common among many poor African American mothers. Fortunately, therapy was not terminated prematurely; the therapist's close attention to the client's perception of her role as well as the role of the child welfare agency led her to arrange a session with the client. The purpose of this session was to clarify these roles and create some distance between the therapist and the outside agency. As a result, the therapist discovered further that the client would not officially adopt Carl because "in her view and in Black culture one never terminates a mother's rights to her child even if someone else raises him and becomes his de facto mother" (p. 173). Once these issues were clarified and the roles of the therapist and the child welfare agency were delineated clearly, the therapist was able to regain the client's trust and continue with the proposed treatment plan.

3. *Learn the family system.* Before school psychologists can effectively match interventions with the needs of the family, it is necessary to determine the structure of the family system. The following areas of family functioning are particularly important to consider: family composition, family members' roles and responsibilities, family's interactional patterns, family's support system, family's childrearing practices, and the family's beliefs about the child's handicapping condition and its source. Once the school psychologist has determined the relevant aspects of the family system, interventions can be individualized and tailored to the particular needs and resources of the family.

For example, in considering family structure, Boyd-Franklin (1989) points out that African Americans will likely have at least some regular involvement with extended family members. For this reason, she emphasizes the need for any service provider working with African Americans to take the time to learn about the relationships that clients have with extended family members. Similarly, Ruiz and Padilla (1979) explain that when working with Latinos, it is important to remember that in addition to nuclear family relationships, Latino family relationships include certain formalized kinship relations such as that of the godfather.

SUMMARY

The purpose of this chapter was to provide school psychologists with a foundation from which to begin to build their skills in providing services to families whose cultural backgrounds differ from their own. Several key concepts were defined in an attempt to aid school psychologists in determining the important dimensions along which families differ, including ethnicity, race, socioeconomic status, and level of acculturation. In addition, a framework for understanding how family systems function was presented from a cross-cultural perspective, and strategies for developing cross-cultural competence were offered. The chapter concluded with a summary of useful guidelines for gathering culturally relevant information about families.

As a result of the rapidly changing demographics of the United States and the concomitant implementation of PL 99-457, school psychologists are faced with the challenge of providing services to culturally different children and their families. Many school psychologists feel ill-prepared to embark on this mission because they have not received adequate instruction or experience through their training programs. The strategies, guidelines, and suggestions offered in this chapter will provide school psychologists with useful ways to begin to develop the skills necessary for working effectively with culturally different families. It is important to understand that acquiring these skills is a lifelong process. Learning about another culture and developing the skills to communicate effectively with its members is a process that begins with the first family with whom we work and improves over time as our number of cross-cultural interactions and experiences increase. Once we make a commitment to developing cross-cultural competence, the knowledge that we gain about ourselves and others and the cross-cultural interactions that we experience will be forever enriching.

Best Practices in Working with Parents of Children with Disabilities

Marian C. Fish
Queens College of the City University of New York

OVERVIEW

Relationships between school professionals and parents of children with disabilities have changed dramatically over the last century. This shift in family–professional relationships has greatly influenced best practices of school psychologists working with parents of children with disabilities.

Prior to the 1960s parents were expected to follow the recommendations of professionals rather than to participate in decision making (Turnbull & Winton, 1984). Fine and Gardner (1994) remind us that parents were often blamed for their children's problems and treated poorly. They describe this phase of involvement as one of "passivity on the part of the parent" (p. 2).

As a result of the political advocacy of such parent organizations as the National Association for Retarded Children and other activist groups and greater interest by professionals in the rights of families, legislation passed in the 1970s reflected a shift in policy toward mandated parent participation in educational planning for children with disabilities. Rights given to parents in PL 94-142, the Education for All Handicapped Children Act of 1975, for example, included required notice and consent for evaluation and participation in decisions regarding evaluation results and at IEP conferences. While parent participation increased dramatically and many professionals recognized the importance of family involvement, parents were not always prepared for active participation and school policies often did not encourage parent involvement. During this second phase of family–professional interaction, the continued use of the medical model of help giving fostered dependency of parents on "professional prescribers." "Parents were typically expected to implement the treatment that was prescribed by experts" (Fine & Gardner, 1994).

The ideological shift that has brought us to the current phase of family–professional interaction is the acknowledgment of the rights of parents to participate in the development of programs for children and the recognition that parents and families have strengths, resources, and expertise that can and should be used to meet the needs of their children (Fine & Gardner, 1994). This new perspective can be seen clearly in the Part H requirements of PL 99-457 (1986); this extends PL 94-142 to children below age 5 and requires services to be directed at *families* through the Individualized Family Service Plan (IFSP) which includes a statement of family strengths as well as needs. The primary systems in the life of a child are the home and school, and the message of this legislation is that participation by each system and collaboration between these systems is necessary for the healthy development of the child.

School psychologists have always worked extensively with children with disabilities in special education and to varying degrees with their parents. The "inclusion" movement, which supports placement of children with disabilities into the mainstream whenever possible, will likely further expand the need for the school psychologist to work with parents of children with disabilities in developing viable educational programs.

This chapter describes how school psychologists can effectively apply the philosophy of parent–professional collaboration in their work with children with disabilities. It recognizes that there is not one type of relationship between parents of children with disabilities and school psychologists. The ultimate goal of the relationship is to promote healthy family functioning and parent decision making and to empower parents.

BASIC CONSIDERATIONS

When there is a child with a disability in the family, there is an impact on family functioning (Turnbull & Turnbull, 1990). "Children with disabilities inevitably challenge families by making inordinate demands on their time, psychological well-being, relationships, economic resources, and freedom of movement" (Brantlinger, 1991, p. 250). While there are many similarities in functioning in families with an exceptional child, adaptation of these families can vary greatly and is influenced by a number of factors including ethnic and cultural background, nature of the disability, and family position in the life cycle.

To work successfully with parents of children with disabilities, school psychologists need to be aware of commonalities in functioning and experiences of families with children with disabilities; that is, how are these families alike? Next, it is necessary to consider variables that may affect family adjustment and contribute to the uniqueness of each family. Finally, school psychologists should recognize adaptive coping responses: What does healthy adjustment look like in families with children with disabilities?

Common Family Experiences

Economic realities. Expenses related to a child with a disability often result in financial hardship for families (Turnbull & Turnbull, 1990). Although medical insurance may reduce some of the expenses for medical care, therapy, child care, and special equipment, it rarely provides for all needs (Darling, 1991). Transportation, laundry, or structural modifications for the home to accommodate a child (e.g., ramps) or to repair damage are often costly (Fish, 1991). There are also indirect costs for these families such as lost work time and interference with career advancement. A chance to relocate to another city might have to be rejected because needed child services are not available, and this may prevent a parent from moving upward in his or her company. Funds may not be available to provide for higher education and/or other needs of siblings.

Costs may be high not only for children with severe disabilities but also for those with mild and moderate disabilities; for example, a learning disabled child might need tutoring, summer programs, or a special computer (Turnbull & Turnbull, 1990). The economic impact on families with disabled children can be quite significant.

Daily care needs. The physical and health needs of children with disabilities often require great effort, particularly when the disabilities are severe or the illnesses are chronic. Daily care includes bathing, dressing, toileting, and feeding the youngster as well as cooking, cleaning, washing, and taking care of the household. Going to the doctor, supermarket, or to a fast food outlet can be a major undertaking. Once the child is dressed, he or she must be "taken" in and out of transportation (e.g., car or bus) and moved from place to place. The responsibility of daily care over many years is associated with increased parental stress (Turnbull & Turnbull, 1990). One parent describes a shopping trip with her daughter who is mentally retarded:

> When Beckie was little, such an excursion required only the extra energy needed to carry her on my hip and choose groceries one handed ...But, when she hit her teens a completely new ingredient was added to the challenge. I took her shopping with me only if I felt up to looking groomed, cheerful, competent, and in command of any situation, so that when she bellowed and stamped as she did when we walked through the supermarket door, people who stared could quickly surmise that I would handle the situation, quiet my strange child, and get on with my shopping. (Turnbull & Turnbull, 1985, p. 144)

Socialization needs and recreational opportunities. It has been well documented that parents who have a child with a disability are less frequently engaged in leisure-time activities and interact socially less with friends (Fish, 1991). Parents express feelings of isolation and find it more difficult to go on family trips, out to dinner, or to the movies. Frequently, their social life is limited because of the difficulties in finding a babysitter or care giver who often must be specially trained.

Just as parents' social interactions are curtailed, children with disabilities are often lonely. Meeting the socialization needs of the child with a disability may be stressful as many of these youngsters have significant social handicaps. Negative attitudes of community members is often cited as a major barrier to socialization for the whole family (Turnbull & Turnbull, 1990). For example, when disabilities are very stigmatizing (e.g., severely impaired speech) parents often structure their lives to avoid social situations where the child would have to speak, limiting their social interaction as well (Darling, 1991).

Future planning considerations. A major issue that must be faced is planning for the child when he or she is no longer eligible for mandated services (Darling, 1991). "Most parents of disabled children have concerns about the future from the day they suspect that something is wrong with the child" (Darling, 1991, p. 81). They often ask, "what if something happens to us?" Uncertainty about the future with regard to employment, social opportunities, and legal/financial needs is a common worry that impacts on family planning.

Parent response. Theories that have been proposed to explain the response of parents when learning that their child has a disability include stage theory and nonsequential stage theory (Brantlinger, 1991; Darling, 1991). Stage theory suggests that all families go through a sequential series of stages such as shock, denial, sadness, anger or anxiety, adaptation, and reorganization before generally reaching a final acceptance stage. Nonsequential stage theorists agree that these reactions may be present but believe that the reactions do not necessarily occur in a set order, and may recur at different points in the life cycle. A variant of this view is held by Olshansky (1962) who describes "chronic sorrow" as a normal reaction to the birth of a child with a disability that remains with parents throughout life, often emerging when developmental milestones are reached. More recent opinions suggest that families may have similar responses, but if and when families pass through stages is dependent on a number of variables (Darling, 1991).

Variables Affecting Family Response

All families share many characteristics, and all children present a host of challenges and responsibilities to their parents, yet there is great diversity among families (Hanson & Hanline, 1990; Powers, 1991). A number of variables impact on the adjustment of a family to a child with a disability. For example, Hanson and Hanline (1990) list child characteristics (e.g., age, diagnostic categories, caregiving demands, behavioral characteristics), parent ability to cope with stressors in general, parental beliefs about the cause of the disability, and types and availability of both formal and informal systems and networks of support (e.g., family, friends, professionals) as contributing to the adaptation and stress experienced by families of children with disabilities. Other researchers have identified variables such as socioeconomic status, physician attitude, presence of other children and spouse in the home, prior information, religiosity, physical appearance of the child, and prognosis (Darling, 1991). For the purposes of this chapter, these variables have been combined and organized as follows: nature of disability, cultural background, family structure, and family's position in the life cycle

Nature of the disability. The nature, severity, and demands of the disability play a critical role in family response (Turnbull & Turnbull, 1990). Each type of disability has distinctive characteristics and functional behaviors that impact on the family. For example, when a child has a language or speech disorder, everyday communication may be affected (Turnbull & Turnbull, 1990). In a recent study, 28% of parents of children with a wide variety of disabling conditions indicated that the disability impacted on the daily lives of the family; the effect was "clearly more pronounced among the families of children with more substantial handicaps and rises to 60% for families of children with physical/multiple impairment" (Palfrey, Walker, Butler, & Singer, 1989, p. 102).

The physical appearance of the person with disabilities can influence family reaction. A very visible handicap may affect not only the child's self-concept but also the attitudes of parents, siblings, and others in the community. Severe disabilities that are more visible may excuse inappropriate behavior or may cause social stigma (Turnbull & Turnbull, 1990). It is not clear, however, that parents always share a common view of severity of handicap (Blacher, 1984). Ambiguous conditions such as autism or those with uncertain prognoses are hypothesized to be the most emotionally stressful for families as parents often keep searching for plausible diagnoses or appropriate treatment (Brantlinger, 1991). Genetic disorders have broad implications because parents may be carriers of the trait (Brantlinger, 1991). When parents have negative attitudes toward deviance prior to the birth of the child, a more difficult adjustment may occur (Seligman, 1991). This suggests that a thorough understanding of parents' feelings about the disability and of their expectations for the child is essential.

Of course, a most critical aspect of the disability is the functional behavior of the child. It is not the disability itself that is the key, but the resulting behavioral characteristics which impact on the family.

Cultural background. There is great diversity of reaction to childhood disability dependent on subcultural groups. A family's beliefs, values, customs, traditions, and the ways it accesses health care will affect its adjustment to disability. Seligman and Darling (1989) identify four major subcultural categories: (a) social class, (b) race/ethnicity, (c) religion, and (d) region. However, care must be taken not to stereotype any group.

The clearest examples of social class differences have occurred in studies of children within the mild ranges of retardation. Parents and professionals from middle- and upper-class families regarded even mild retardation as devastating, while lower-class parents "may not even define it as a disability" (Seligman & Darling, 1989, p. 189). Possible explanations are that lower-class families are not as achievement oriented and were able to envision their child in normal adult roles or that they have a higher tolerance for deviance. In the case of a physical disability, however, there appeared to be no differences by social class. A recent study reported that lower-class families had less family support and more physical, emotional, and financial problems than higher-class families (Seligman & Darling, 1989). It is hypothesized that when necessities are scarce, the child's disability is only one of a myriad of problems and may not get the same attention as in more affluent families. The results of still another study indicate that parents from different socioeconomic groups will report stress differently and will behave differently with regard to participating in program planning (Palfrey et al., 1989).

Attitudes toward disability in our society vary by ethnicity and religion, yet we must be careful not to stereotype any group as there is much intragroup variability. Also, there is considerable confounding in studies of ethnic groups, religious groups, and social class.

Research on African-Americans, for example, indicates that they place great importance on the extended family and the church as social support and that they report a greater number of significant others who assist families with a disabled child (Seligman & Darling, 1989). Hispanic subcultures include Mexicans, Puerto Ricans, and subgroups from many Latin American countries. Traditional Mexican culture values familism, male dominance, subordination of young to old, and person orientation rather than goal orientation (Seligman & Darling, 1989). These values and child-rearing attitudes may result in Mexican-American parents being more accepting of disability than Anglo parents. Similarly, family strength and support is very important in the Puerto Rican community along with submissiveness and acceptance of fate; such "fatalism may help parents cope with a child's disabilities" (Seligman & Darling, 1989, p. 200). Another situation where culture may play a role is among Asian-Americans. In Chinese culture the oldest son usually has more responsibilities than other children in the family, and if he is disabled, this may create difficulties (Seligman & Darling, 1989).

There is no clear relationship between any religious group and acceptance of disability. It is suggested, however, that more religious families may have support networks through their church or synagogue that may facilitate acceptance and coping (Seligman & Darling, 1989).

It is clear that cultural background is a significant factor in family adjustment to a child with a disability and that it also affects family responsiveness and receptivity to sources of help (Fine & Gardner, 1994).

Family structure. Family structure refers to the characteristics of the family, its members and organization. Persons in the family — mother, father, siblings, grandparents — join together to perform various tasks or functions; all have different roles and responsibilities (Fish & Jain, 1988; Powers, 1991).

An increasing number of children with disabilities are being raised in nontraditional households such as single-parent, blended, or multigenerational homes (Fish, 1991). For example, an overwhelming majority of single parents, 95%, are mothers who work outside the home (Lombana, 1983). While the functions of the single-parent family are the same as the two-parent family, when the custodial parent tries to carry out both functions, role strain may result (Fish, 1991). On the other hand, in blended families or step families, where one or both partners have been previously married, a major structural issue is the lack of clear role definition and clear boundaries (Fish, 1991): This is the opposite situation to a single-parent household because there are now more than two parents with potential conflict in such areas as visitation, life-style, and/or discipline (Fish, 1991). It is clear that alternative family structures must be carefully considered and play a critical role in adaptation when there is a child with a disability.

Factors such as the sex of the child, visibility, and/or severity of the disability may affect the responses of individual family members. There are data to suggest that mothers may have more demands placed on their time as a result of role division in the family (McLinden, 1990). Some research suggests that siblings of children with disabilities may be prone to adjustment problems (Hannah & Midlarsky, 1985). There is some evidence that when a sibling has excessive responsibility for a brother or sister with a disability, this is related to the development of anger, guilt, and resentment (Seligman, 1991). Several studies indicate that older female siblings in small families may have more extensive care-taking responsibilities than other siblings. It is apparent then that family subsystems, mother, father, parents, and siblings, all affect and are affected by the exceptional child in the family and contribute to the uniqueness of each family's adjustment.

Life-cycle position. Families progress through identifiable, predictable stages in their development (Carter & McGoldrick, 1989). Whether these are crises or transitions depends on the ability of a family to modify its structures to accommodate changing needs (Carlson, 1987). A survey of the literature suggests that major stages for families with a child with a disability are at preschool age (3–5 years), school age (6–8 years), adolescence (12–14 years), and chronological adulthood (19–21 years) (Beavers, Hampson, Hulgus, & Beavers, 1986; Powers, 1991). For example, with a retarded child during the early years, there are issues concerning the child's physical health and safety, parent adjustment to a diagnosis and readjustment of expectations (Powers, 1991). When the disabled child reaches school age, parents may be forced to acknowledge once again their child's widening differences from other youngsters. For parents of children with retarded development the onset of puberty increases their awareness of differences between their child's physical appearance and his or her mental and social abilities (Wikler, 1981). The adolescent may have increased wishes for independence, and his or her emerging sexuality is evident. At a time when the nondisabled adolescent is entering independent adulthood, the adolescent with a disability is often still dependent on the family. Parents who anticipated increased freedom and independence in personal, professional, and family areas must readjust their expectations (Dane, 1993). In one study of development and transition involving 30 parents of mentally retarded persons, their child's 21st birthday was characterized as the second most stressful of 10 predictable crises (Wikler, 1981).

Adaptive Coping

Despite oft-repeated statements of greater chronic dysfunction in families of children with disabilities, there is little evidence that supports the presence of greater psychopathology among these families (Hampson, Hulgus, Beavers, & Beavers, 1988). Although some families adapt better to the stress of a disabled child than others, most families manage to adapt quite well to the requirements of a child with special needs.

In a study of families with a retarded child, for example, observed family competence was within the adequate range and compared favorably to the nonclinical group of families (Hampson et al., 1988). Characteristics associated with healthy adaptation included (a) openness and directness of communication, (b) strong internal support systems, (c) a noticeable degree of autonomy and responsibility in all members, and (d) few signs of unresolved conflict. Expression of feelings did not necessarily have to be positive; it could be negative or ambivalent and still indicate good coping. In another study, family adaptation was promoted by clear diagnosis and information about the disability and the capability for positive contact with and response to other family members (Beavers et al., 1986). Families that acknowledged the extra needs and the differentness of the disabled member, while giving other family member needs and views equal weight, were most competent. In these families there was an effort made to balance the special needs of the disabled child with other family concerns (Beavers et al., 1986). Still other studies have reported that adequate social support and financial and personal resources such as family integration, parental self-esteem, and physical and emotional health were associated with fewer negative consequences (Todis & Singer, 1991). Morgan (1988) reports that family cohesion, expression, and recreational orientation as well as the mother's perception of adequacy of support from the husband and other relatives were associated with better adaptation to an autistic child.

In general, certain family characteristics appear to be associated with healthy adjustment. These include good communication among the family members, supportiveness of family members towards each other, and the ability to assume appropriate parent and child roles (Fine & Gardner, 1994).

Background and Training

Working successfully with parents of children with disabilities requires that school psychologists move from a child-centered model to a family-centered model. A family orientation in school psychology is not synonymous with family therapy but rather refers to consideration of the child within the family context. It recognizes that families have strengths and supports, and it appreciates their diversity and uniqueness. An understanding of similarities and differences among families and recognition of adaptive functioning as just discussed is essential. A knowledge base in family systems is required as all members of a family influence and are influenced by other members. The family is a dynamic entity and should be approached in a manner that recognizes the developmental and cyclical nature of adaptation (Bailey & Simeonsson, 1988). A family orientation does not subscribe to a deficit model, but rather it builds on existing family competencies and helps develop new competencies so that a family can actively advocate for itself.

It is helpful if the school psychologist working with families with a disabled child not only has a systemic perspective but also has knowledge about (a) the contemporary family (e.g., single-parent, blended, extended); (b) the cultural/ethnic background of families within the district including their values, traditions, beliefs, and view of health care; (c) relevant community resources; and (d) the specific disability and the behavioral aspects of the disability.

A number of skills for effectively working with parents follow from the knowledge bases described. Fine and Gardner (1994) note five "process skills" that support the enactment of collaboration:

> 1. Interpersonal skills (e.g., accurate listening and communicating).
>
> 2. Language considerations (e.g., "we" rather than "I" statements, respect for others' views).
>
> 3. Problem-solving skills.
>
> 4. Recognition of family prerogatives.
>
> 5. Ability to personalize assessment (e.g., assess families with regard to structure, function, strengths, and resources). (p. 20)

Table 1 illustrates the types of helping behaviors likely to be enabling and have positive consequences (Dunst & Paget, 1991, p. 36).

In a fascinating study of low-income, black, single-mothers, behaviors in unempowering and empowering relationships were identified (Kalyanpur & Rao, 1991). Disrespect, a focus on deficits, and a discounting of differences in parenting styles led to unempowering relationships. Behaviors in empowering relationships included (a) responsiveness to parent's needs by providing emotional support and specific services and (b) establishment of rapport by being conversational, interpreting what was said, sharing stories, and expressing confidence in the mothers' ability to bring up their children.

It is also important for the school psychologist to be able to identify potential obstacles to a parent–professional relationship and have the skills to overcome them. Sometimes, however, these obstacles are bureaucratic and require major organizational change.

Finally, consultation skills, which are now an integral part of the curriculum of many training programs, will facilitate interactions with parents and the development of a collaborative relationship. These skills include expertise in communication and problem solving (Fine & Gardner, 1994).

TABLE 1
Help Giver Attitudes, Beliefs, and Behaviors Associated with Empowering and Competency-Producing Influences

Prehelping attitudes and beliefs	Helping behaviors	Posthelping responses and consequences
1. Positive attributions toward help seekers and helping relationships.	1. Employs active and reflective listening skills.	1. Accepts and supports help seeker decisions.
2. Emphasis on help seeker responsibility for meeting needs and solving problems.	2. Helps client clarify concerns and needs.	2. Minimizes the help seeker's sense of indebtedness.
3. High expectations regarding the capacity of help seekers to become competent.	3. Pro-offers help in response to help seeker needs.	3. Permits reciprocity as part of help giver–help seeker exchanges.
4. Emphasis upon building on help seeker strengths.	4. Offers help that is normative.	4. Minimizes the psychological response costs of accepting help.
5. Proactive stance toward helping relationships.	5. Offers help that is congruent and matches the help seeker's appraisal of needs.	5. Enhances a sense of self-efficacy regarding active involvement in meeting needs.
6. Promotion emphasis as the focus of help giving.	6. Promotes acquisition of competencies to meet needs, solve problems, and achieve aspirations.	6. Maintains confidentiality at all times; shares information only with help seeker's permission.
	7. Employs partnerships and parent–professional collaboration as the mechanisms for meeting needs.	
	8. Allows locus of decision making to rest with the help seeker.

BEST PRACTICES

Traditional means of working with parents of special needs children have often been paternalistic and have led to dependency on the professionals. Despite pleas for family involvement, there is often a disparity between the approach to helping which views the school psychologist as being the authority with all the answers and the behaviors necessary to promote greater participation on the part of the family (Dunst & Paget, 1991).

A number of models proposed for working with parents of special needs children have attempted to address this conflict. The model developed by Dunst, Johanson, Rounds, Trivette, and Hamby (1992), for example, sees parent–professional partnerships as a function of interactive time between parents and professionals and the display of different behavioral states and traits such as trust, honesty, and shared responsibility (p. 170). This model shows how relationships evolve from coordination to cooperation to collaboration and finally to a partnership "as parents and professionals work toward agreed upon goals" (p. 169). Reaching a true partnership relationship is a process that takes time. Table 2 (Dunst et al., 1992, p. 163) presents a categorization scheme for organizing the major characteristics of parent–professional partnerships as identified by *both* parents and professionals. These characteristics can be used by professionals as guidelines to evaluate their own performance with regard to attitudes, beliefs, and behaviors.

A model of collaborative consultation is presented by Fine (1990, 1991). Its objectives include (a) educating parents for decision making and including them in decision making, (b) assisting them therapeutically to improve coping behaviors, and (c) enabling and empowering parents to actively support their child. Multiple roles are seen for the school psychologist including mediator, advocate, therapist, and expert. As with the parent–professional partnership model of Dunst et al. (1992), collaboration is a desirable goal that takes time to achieve.

Laborde and Seligman (1991) propose a model of intervention for working with families of disabled children that has three counseling interventions: educative, personal advocacy, and facilitative counsel-

TABLE 2
A Categorization Scheme for Organizing the Major Characteristics of Parent–Professional Partnerships

Category	Definition	Characteristics
Beliefs	Cognitive attributions about how one should act or ought to behave toward other people	Trust, mutual respect, honesty, acceptance, mutually supportive, nonjudgmental, presumed capabilities
Attitudes	Particular (emotional) feelings about a person, situation, or relationship	Caring, understanding, commitment, empathy, positive stance, humor, confidence
Communicative Style	Methods and approaches for information sharing between partners	Open communication, active listening, openness, understanding, full disclosure of information, information sharing
Behavioral Actions	Behaviors that reflect translation of attitudes and beliefs into actions	Mutual respect, openness, flexibility, understanding, shared responsibility, mutual support, reciprocity, mutual agreement about goals, dependability, equality, humor, problem solving

Note. From "Characteristics of parent–professional partnerships" by C. J. Dunst, C. Johanson, T. Rounds, C. M. Trivette, and D. Hamby. In S. L. Christenson & J. C. Conoley (Eds.), *Home–school collaboration: Enhancing children's academic and social competencies.* Silver Spring, MD: National Association of School Psychologists. Copyright 1992 by NASP. Reprinted by permission of the publisher.

ing (p. 348). The educative role is one of providing information to parents; personal advocacy refers to assisting parents in finding relevant information and locating appropriate services but being careful to help parents assume this role themselves. Facilitative counseling is similar to supportive counseling or psychotherapy to help parents deal with feelings or behaviors of concern and to build coping behaviors.

A review of these and other models suggests that there is considerable agreement as to what effective relationships between school psychologists and parents look like, and much consensus on the means to achieve these goals. Best practices in working with parents of children with disabilities has as its goal collaboration and/or partnership with parents using approaches that empower, encourage participatory involvement, and enhance competency (Dunst et al., 1992). Professionals move in and out of the life of the child, but parents provide constant support for their children and hold ultimate responsibility for their well-being.

Best practice in working with parents of children with disabilities include the following services:

Education/Information sharing. The role of providing information means that school psychologists help parents obtain information, understand and interpret information, or use information to help make decisions. The types of information can include behaviors associated with the disability, characteristic patterns of development, health or related services, and community resources. Care must be taken to ensure that siblings and/or other family members are also informed during this process.

Information needs will vary at different age periods (Blacher, 1984). For example, diagnostic and prognostic information is generally conveyed at earlier ages (Seligman & Darling, 1989). On the other hand, information on sex management and sources of vocational training is more likely to be requested during adolescence. Other information needs are quite consistent across ages and include inquiries about respite services, financial assistance, support groups, and appropriate child-care providers.

At any age of the child, parents may want practical information regarding management, specialized equipment, or legal rights, all of which may be provided through books and other reading materials as well as through referrals to community organizations. A list of 60 books written by parents of children with many different disabilities has been prepared by Mullins (1987) and is an excellent bibliographic resource. The National Information Center for Children and Youth with Disabilities (NICHCY, P.O. Box 1492, Washington, DC 20013-1492) is a national information and referral clearinghouse and provides material for parents and professionals. Also, the Association for the Care of Children's Health Resource Catalogue (ACCH, 7910 Woodmont Avenue, Suite 300, Bethesda, MD 20814) lists a number of useful publications.

Because information may come from many sources, Powers (1991) sees one role of the school psychologist as facilitating and coordinating service access. As a liaison to medical, educational, social, and financial services, the school psychologist can slowly transfer this knowledge of services to the family. One father's plea for such a coordinator is seen here:

> It seems that ever since Joan was born, everything has changed . . . there always seems to be at least three experts around giving Judy advice on how to handle Joan . . . I know that my son Jimmy has been having some problems, but the thought of another expert . . . is more than I can take. I wish we could find one person who could pull all the information together. (Family Life, 1985, p. 50)

Once all the information is gathered, parents may choose to collaborate with the school psychologist in decision making. An essential aspect of this collaboration is that parents be given options whenever they exist so that they can make educated decisions on behalf of their child (Apter, 1992). A problem-solving approach involving problem identification and analysis, brainstorming alternatives, and choosing a plan of action not only is a collaborative process but also models the problem-solving procedure for families.

Helping to ensure an appropriate match between family needs and service opportunities is a critical responsibility of the school psychologist. Providing services congruent with the needs of family may mean problem solving with parents on the phone rather than in person so they do not miss work. Care must be taken not to overburden families but rather to reinforce their decision-making abilities.

Advocacy. Advocacy "refers to the process of aiding parents to actively and purposively work for their own and their child's welfare by obtaining the support and services they need" (Laborde & Seligman, 1991, p. 361). This may involve overcoming physical barriers such as stairs, cultural barriers such as prejudice, or social barriers such as needed services (Seligman & Darling, 1989). As seen in the education role described earlier in this chapter, the school psychologist has the requisite knowledge about how agencies operate and how referral services work. Powers (1991) suggests that the school psychologist move from being a direct advocate for the child and family to being a consultant to parents in the advocacy process. Once again this means a relinquishing of authority on the part of the school psychologist and supporting the family as it asserts itself.

Support. Social support has been identified repeatedly as a key component in healthy family adaptation and coping. Support networks can be formal, such as organized groups run by the National Association of Retarded Citizens or the local school, or informal such as family, extended family, and friends. Often families have resources other than the schools available to them. For example, the church or synagogue may be a nurturing environment for its members. Maintaining existing social networks and developing new social networks help reduce the social isolation and stresses of the family with a child with a disability. One useful source of information is the *Parent Resource Directory* available from the ACCH (address given earlier). This guide provides a listing by state of parents of children with special health needs who are willing to network. Of particular importance in all cases is to consider support not only for mothers but for fathers and siblings as well.

Facilitation of healthy family functioning. Promoting healthy family functioning requires school psychologists to support the structural balance within the family including clear boundaries between parental and child subsystems, the executive function of the parental subsystem and a healthy relationship between the parents (Powers, 1991). It is important to acknowledge the extra needs and differences of the child with the disability without neglecting other family members. Remember parents have needs beyond those of educating their children. Family competencies and resources can be assessed informally or through the use of specific assessment measures such as those described by Bailey and Simeonsson (1988). Noncustodial parents should be included in decision making when appropriate and information should be sent to all involved adults.

Parents must determine if they want help and what kinds of help they need. Some ways to assist families might include helping them to minimize or better manage time demands and/or to encourage parents to maintain their own health through such means as exercise and vacations. Another suggestion is to hold informal family meetings weekly to review household responsibilities and discuss concerns.

Individualization of services. In all cases the relationship between the school psychologist and the parents is an individualized one taking into consideration racial, ethnic, cultural, and socioeconomic diversity as well as the nature of the disability, family structure, and life cycle position. For example, early childhood consultation with families regarding young children with disabilities is qualitatively different from consultation when children are in elementary and secondary school settings (Mowder, 1994). These younger children are developmentally more dependent on parents and families for their care and protection (Mowder, 1994). Parents should never be expected to function in only one way, and school psychologists must match services to need.

Other best practices. Best practices in working with all parents should be applied to families with disabilities as well. Some examples include avoidance of jargon, flexible scheduling, addressing correspondence to both mother and father, considering siblings, and establishing a relationship before there is a crisis (e.g., Fish, 1990). Parent–teacher contacts will likely increase as a result of including more children with disabilities in mainstream classes. School psychologists can assist teachers and other school personnel in acquiring skills important for successful collaborative relationships with parents.

SUMMARY

This chapter has identified a number of common experiences among families with children with disabilities. These are economic constraints, daily care needs, socialization needs, and worries about the future. Though these families share many concerns, each family is unique and a number of variables impact on their adjustment including the nature of the disability, the cultural background, and family structure, and the family's position in the life cycle. Adaptive functioning in families with children with special needs is associated with good communication, strong support networks, and clear boundaries between subsystems.

Working successfully with parents requires school psychologists to adopt a family-centered approach to services. This is reflected in a nonblaming perspective where family strengths and resources are recognized and supported, and different methods of coping are respected. The goal is one of collaboration with parents to enable and empower them so that they may help themselves. This involves the development of trust, respect, mutual commitment, and sharing. Empowerment of parents is facilitated by the school psychologist through information sharing, advocacy, support, promoting healthy family functioning, and individualization of service to each family. In all of these roles the school psychologist aims to increase parents' involvement so that they assume the role of decision-makers for the family.

ANNOTATED BIBLIOGRAPHY

Bishop, K. K., Woll, J., & Arango, P. (1993). *Family/professional collaboration for children with special health needs and their families.* Available from Association for the Care of Children's Health (ACCH), 7910 Woodmont Avenue, Suite 300, Bethesda, MD 20814.
This monograph reviews seven principles of family/professional collaboration that include behaviors, beliefs, attitudes, and values that must be present in a collaborative relationship. It gives specific family, community, state, and national examples of programs that use collaborative practice.

Christenson, S. L., & Conoley, J. C. (1992). *Home–school collaboration: Enhancing children's academic and social competence.* Silver Spring, MD: National Association of School Psychologists.
This volume provides information to facilitate the development of successful home–school partnerships so that children's educational and mental health concerns can be addressed effectively. It includes both theoretical and practical chapters that provide information on specific programs and approaches to intervention.

Fine, M. J. (Ed.). (1991). *Collaboration with parents of exceptional children.* Brandon, VT: Clinical Psychology Publishing Co.
This volume has as its theme the empowerment of parents so they can become active partners in meeting the needs of their own children. It begins with an overview of the family and exceptionality and then covers important educational and intervention considerations. There is a section on the impact of different exceptionalities on the family and a discussion of some critical topics such as sexuality, transitions, and advocacy.

Seligman, M. (Ed.). (1991). *The family with a handicapped child.* Boston, MA: Allyn & Bacon.
The second edition of this book deals with all aspects of exceptional families and is written for professionals in mental health, educational, and medical settings. It includes chapters on siblings and fathers as well as chapters on specific types of disabilities.

Turnbull, A. P., & Turnbull, H. R. (1990). *Families, professionals, and exceptionality: A special partnership.* Columbus, OH: Merrill.
This is an easy-to-read, comprehensive, and practical guide to understanding the special partnership of families with exceptional children and professionals who work with them. Its emphasis is on applying family-systems theory in professional practice. It is filled with clear and helpful examples.

91

Best Practices in Working with Students with Traumatic Brain Injury

J. Michael Havey
Eastern Illinois University

OVERVIEW

The recent revision and renaming of federal special education legislation mandated services for a new category of exceptionality, traumatic brain injury (TBI). Although the category is new, the disability is certainly not, nor is it rare. In fact, TBI is the number one killer and disabler of children and young adults in this country. The tragedy of this condition is intensified because it is unforeseen and unexpected. A young person can be inexorably robbed of abilities and skills overnight. As medical technology has improved so have survival rates of those who have sustained this type of injury. Increasing numbers of children with TBI are returning to schools who are then called upon to be major providers of long-term rehabilitation for these individuals. School psychologists knowledgeable about this disability can play a meaningful and important role in providing these services.

Educationally, TBI is defined as an acquired injury to the brain caused by an

> external physical force, resulting in total or partial functional disability or psychosocial maladjustment that adversely affects educational performance. The term applies to open or closed head injuries resulting in mild, moderate, or severe impairments in one or more areas, such as cognition; language; memory; attention; reasoning; abstract thinking; judgment; problem-solving; sensory, perceptual and motor abilities; psychosocial behavior; physical functions; information processing; and speech. The term does not apply to injuries that are congenital or degenerative, or brain injuries induced by birth trauma (Individuals with Disabilities Education Act of 1990).

As do other categories of educational disability, this definition excludes some children. The present educational definition includes children who are adversely affected by "an external physical force." It explicitly excludes those children whose brains may have been affected by congenital or degenerative conditions (e.g., hydrocephaly, microcephaly) as well as those whose brains may have been injured by birth trauma. The definition also omits mention of those children who might suffer from an "internal" incident such as a vascular accident.

Brain injury caused by external physical force is typically divided into two major classes: open and closed. Open brain injury results when the skull is penetrated by a foreign body, as in gunshot or missile wounds. Resultant damage is often focal rather than diffuse. Closed brain injury, the most common type among children, results when a moving object (e.g., baseball bat) strikes the stationary head causing a sudden jolt (acceleration injury) or when the moving head is abruptly stopped or slowed by a stationary object (e.g., car dashboard; deceleration injury). In contrast to penetrating or open head injury, damage resulting from closed head injury is almost always diffuse due to both the nature of the physical agent involved and characteristics of the human brain and central nervous system.

The brain is of a gelatin-like consistency. Strong impacts cause the brain to move in a rippling manner inside the skull. Twisting and tearing of tissue often results from this movement. This damage is exacerbated by the fact that the inner surface of the skull is rough and rigid. The movement of the brain across this surface causes additional tearing.

Damage obviously occurs at the point of impact (coup) in a closed head injury. Additional damage also occurs to the area of the brain opposite the site of actual contact (contracoup). In addition to the mechanisms just described — collectively known as "primary" brain damage — closed head injury also often results in "secondary" injuries that can occur subsequent to the initial injury. These include bleeding, swelling of tissue, decreased blood flow, elevated pressure, and infection.

Even though children whose brains have been damaged through internal and congenital processes are excluded, large numbers of children will still potentially be eligible for services under this new category. Trauma to the head from external events such as motor vehicle accidents, abuse, and falls has been estimated to be one of the most common neurological disorders in children (Berg, 1986). Current estimates suggest that between 500,000 and 1,000,000 cases occur per year in the United States (e.g., Begali, 1987; Savage, 1991). Moreover, as medical technology and care have become more sophisticated, the survival rate from TBI has continued to increase. Although young people in the 15-to-24-year-old range are most at risk for TBI, children under 15 are afflicted at almost the same rate (Kalsbeek, McLaurin, Harris, & Miller, 1980; Rosen & Gerring, 1986). TBI occurs in males at a rate approximately twice that in females. Incidence rates are similar for whites and nonwhites. Motor vehicle accidents and falls are the most common causes (Kalsbeek et al., 1980).

BASIC CONSIDERATIONS

Issues of Severity

Because the forces responsible for TBI vary significantly, the severity of the injury varies from individual to individual. A convention among medical personnel is to rate TBI as mild, moderate, or severe based on length and depth of coma and duration of post-traumatic amnesia. Although common usage suggests that a dichotomy exists between coma and consciousness, reality is better represented as a continuum of degrees of consciousness. A metric frequently utilized to measure the severity of coma is the Glasgow Coma Scale (GCS). This technique grades eye, motor, and verbal responses within the first 24 hours following trauma. Numerical values are assigned to different levels of response and a total score (15 points possible) is obtained. Lower scores represent a lesser degree of response and are indicative of more severe injury. In addition to providing an indication of initial severity, the GCS is also employed for monitoring change.

Post-traumatic amnesia (PTA) is defined as the period of time following trauma when the patient is incapable of reliable, consistent, and accurate memory for ongoing events. Under a common classification system, PTA of less than 1 hour is considered mild, PTA of 1 to 24 hours is considered moderate, PTA that continues from 1 to 7 days is considered severe, and PTA of greater than 7 days is considered very severe.

Although these ratings are often employed to provide an estimate of severity of injury and physiological disruption, an important consideration for school psychologists and other school personnel to remember is that they often do not correlate well with future recovery nor provide information useful in predicting outcome. For example, Savage (1991) cited a study that found many children with mild head injury were experiencing serious problems in a variety of contexts. Also cited were many children with severe injury who, with the exception of motor difficulties, were doing as well as the mildly to moderately injured children. Traumatic brain injury is a complex phenomenon and recovery is impacted by a variety of factors. Other variables such as age, causal agent, extent of damage, site of injury, and quality of rehabilitation all interact to influence outcomes for individuals (Begali, 1987). School personnel need to remember that severity of injury is only one bit of information needed to make accurate judgments about a child's potential for recovery.

A related issue of importance to school psychologists who might work with children with TBI is the concept of "plasticity." This term has been applied to the long-held notion that because children's brains are not completely developed, they can recover more rapidly and more completely from brain insult than can adults. Although some evidence does exist suggesting that children may recover language functioning more easily than do adults, other research evidence suggests that trauma to a brain incompletely developed prevents the development of a complete and competent behavioral repertoire (Berg, 1986). Moreover, other evidence suggests that early brain injury may result in more severe long-term deficits than injury sustained later (Shaw & Yingst, 1992). Current beliefs about the limits of cerebral plasticity in children argue against complacency in rehabilitation efforts.

Psychological Sequelae of TBI

As mentioned previously, TBI can vary greatly in severity and the rating of injury severity and physiological disruption does not provide a great deal of insight about recovery. Efforts to help a child be reintegrated into a school setting can be hindered by (a) the lack of correlation between severity of injury and cognitive and behavioral recovery and (b) the lack of consistency between physical and cognitive recovery. The potential often exists for sending a child back to school with little if any academic or social support before he or she has recovered sufficiently. Although apparently well, children who have sustained TBI often experience psychological sequelae that may not be apparent until they are returned to a school setting. According to Levin (1985) memory disorders are the most common and persistent psychological consequences of TBI. Problems of attention and concentration are also frequently experienced by these children as are problems with language production and processing (e.g., word finding, verbal fluency, reading comprehension, and writing; Begali, 1987). Other psychological and behavioral problems associated with TBI include impairments of judgment, flexibility, self-control, family relationships, and age-appropriate behavior (Savage & Wolcott, 1988).

Obviously, any of these impairments could pose serious problems within a school setting for a child who has sustained a brain injury. In addition, educators should be aware that many children are prescribed anticonvulsant medication — as a prophylactic measure to reduce the possibility of seizures —

and/or other medications to help manage behavioral excesses. The possibility exists of cognitive side effects that could influence learning. Therefore, educators should always know the medications prescribed and any possible side effects.

A number of physical deficits can also result from TBI. Rigidity of movement, loss of muscular control, weakness, and loss of balance and coordination are not uncommon sequelae of TBI. School psychologists need to be particularly aware of these factors because of their potential impact on assessment results and classroom performance, two areas of direct concern to the psychologist.

BEST PRACTICES

Best Practices in Assessment

The goal of the assessment process is to gather information and data that will allow educational personnel to address the following questions:

- What are the needs of the student with traumatic brain injury?
- What is the educational interference caused by the traumatic brain injury?
- What are the services and programs necessary to minimize interference . . . [and maximize learning]? (Roth, Harley, Havey, Probst, & Vaal, 1993)

To make the best educational plans and develop the best educational programs for children who have sustained TBI, the school psychologist and other school personnel must complete a broad-based evaluation that provides information relevant to the child's pre-trauma functioning, the nature of the trauma itself, and the child's level of post-trauma functioning. Information regarding pre-trauma functioning helps determine the educational impact of the trauma by providing a baseline against which post-trauma behavior can be judged. Because it is likely that a child who experienced TBI did not have a complete psychoeducational assessment prior to injury, this component of the evaluation focuses primarily on a review of the child's educational record and interviews with adults knowledgeable about the child's previous level of functioning. Group achievement scores, report cards, anecdotal records, and work samples are all important sources of data. Parents, teachers, and other school personnel can provide subjective information that may help shed light on the child's behavior and performance.

A review of medical records and/or interviews with medical personnel and parents can provide valuable information about the severity of the trauma and the overall medical situation surrounding the injury. Moreover, many children will have been evaluated by a hospital psychologist shortly before returning to school. A review of the report and personal contact with the hospital psychologist can also provide helpful information.

In most cases the school psychologist sill need to be directly involved with a complete case-study evaluation conducted by school personnel. Telzrow (1991) suggests that such assessment should incorporate several characteristics. First, she recommends that evaluations of these children incorporate techniques and procedures in compliance with federal and state regulations governing the assessment and education of students with disabilities. Telzrow (1991) also suggests that assessment of students with TBI should incorporate a neuropsychological framework. Because TBI involves neurological dysfunction, this point of view is logical. Although many school psychologists are not very knowledgeable about this branch of psychology, an increasing number are. And the number of graduate programs offering courses and practica in neuropsychology is growing (Hynd, 1981; Stone, Gray, & Dean, 1989). In addition, the National Association of School Psychologists and state associations offer continuing education opportunities to develop an understanding of basic neuropsychological principles and knowledge of TBI in particular. If school psychologists are to effectively serve this population of students they must avail themselves of these continuing education opportunities. School psychologists may also be able to increase their understanding of neuropsychology in general and TBI in particular through consultation with professionals based in a regional education center or a local medical facility.

Thirdly, Telzrow (1991) suggests that assessment of children with TBI be multidisciplinary in nature. Even though federal legislation mandates a multidisciplinary evaluation of all children suspected of a disability, a multidisciplinary evaluation is imperative for children with TBI. TBI affects each child differently and any aspect of the child's functioning can be affected. TBI can have an impact on cognitive processes, language, social behavior, and/or sensory and motor functioning. More so than with other disabilities, the expertise of professionals such as speech-language pathologists, occupational therapists, physical therapists, and medical doctors may be needed in order to develop a comprehensive picture of the child's abilities and needs. A fourth recommendation made by Telzrow (1991) is that assessment of children with TBI should also include contextual assessment. This includes a focus on "moderator" variables — social, environmental, and motivational factors — that influence the child's ability to cope and adjust to the presenting disorder (Ewing-Cobbs & Fletcher, 1990). These factors may not be obvious but they cannot be ignored because they can have a significant impact on the child's functioning in the school setting.

Telzrow (1991), in addition to several other authors (e.g., Ewing-Cobbs & Fletcher, 1990; Obrzut &

Hynd, 1990), suggests that school psychologists take a domain-specific approach to the assessment of children who have sustained TBI. This approach involves the identification and examination of several specific areas of domains of functioning. Although the nomenclature varies somewhat from author to author, domains typically specified include intelligence, language, memory and concentration, sensory recognition and perception, academic achievement, and behavior and personality (see Telzrow, 1991 for lists of major assessment domains suggested by seven experts or teams of experts). Figure 1 provides an illustrative list of instruments and procedures relevant to various domains.

The purpose of this domain-centered approach is "to obtain a comprehensive sampling of performance across the range of behaviors sensitive to neuropsychologic functioning" (Telzrow, 1991, p. 30). This approach is in keeping with the multidisciplinary philosophy because some areas are more appropriately assessed by a particular professional discipline than by another. Moreover, this approach is similar to that taken in many typical psychoeducational case-study evaluations. An advantage of this approach is that it allows for flexibility; the particularities of a child's case may call for an emphasis on some domains but not on others. Some domains only marginally related to performance in school may, nevertheless, provide information about factors that might interfere with the child's progress. The main focus of the assessment should, however, remain on those factors most closely related to school performance.

On a cautionary note, an overemphasis on domains may lead school personnel to ignore information directly related to interventions that can improve school performance and to shift their attention to areas of processing deficit that may provide little information useful for intervention. Caution also needs to be expressed because many of the instruments commonly employed in the assessment of some of these domains have been criticized for their psychometric inadequacies (Reschly & Gresham, 1989; Reynolds, 1989).

During the recovery process the child's level of functioning can change rapidly. For this reason, optimal assessment of the child with TBI will need to be periodic and ongoing. This does not mean that complete psychoeducational batteries need to be administered on a frequent basis. Indeed, many standardized assessment measures are subject to practice effects and tend to be insensitive to small, but important changes in skill level (Kranzler & Shaw, 1992). A methodical system for closely monitoring progress of the child will be important, however. Curriculum-based assessment (CBA) or measurement (CBM) techniques designed for ongoing assessment and for measuring discrete changes in functioning can be important tools in assessment of and program planning for children with TBI.

In addition, CBA and/or CBM techniques can be useful in documenting the adverse impact of the trauma on academic functioning (Shaw & Yingst, 1992) and in helping children and parents understand the need for a gradual and systematic return to school (Ylvisaker, Hartwick, & Stevens, 1991). By comparing performance on post-trauma measures with pre-trauma placement in the curriculum the school psychologist can determine if functioning has deteriorated. Shaw and Yingst (1992) recommend starting the CBA at the place within the curriculum where the child was placed prior to the trauma and testing through progressively lower levels until an instructional level is reached if evidence of decline is apparent.

Regardless of technique utilized, school psychologists assessing children who have sustained TBI need to be alert for signs of the cognitive and behavioral difficulties that are frequent sequelae of TBI. There are, however, several steps that school psychologists can take to surmount this problem. Spreading the assessment over more than one session will probably be appropriate with a child who has difficulty maintaining attention and concentration. "Testing the limits" procedures may also allow greater insight into a child's abilities and skills when test performance is impeded by one of the sequelae previously discussed. Information gained through observation and interview methods will be especially important in the assessment of a child whose behavioral limitations interfere with testing and interpretation of results. Finally, nonstandardized measures such as CBA that allow for greater flexibility in administration can be valuable sources of information.

Best Practices in Educational Planning

Although careful attention needs to be paid to the assessment of children with TBI, its main function is to provide educators with information that can be used to develop an educational program appropriate for the child's needs. An important and somewhat unique problem facing educators who develop educational plans for children with TBI is the transition between a medical environment (hospital or rehabilitation center) and an educational environment. The differences in philosophy, outlook, and system structure all too often contribute to inadequate communication and poorly coordinated services. The return of a student with TBI to a school setting is not a one-time process and may take several weeks. Savage and Carter (1988) identified four steps crucial to ensure a successful transition:

1. Involvement of the school-based special education team in the hospital or rehabilitation facility.

2. Inservice training for all school-based staff who will have contact with the student.

3. Short- and long-term planning for the support services needed for the student.

4. Continued follow-up by the rehabilitation professionals.

The training and background of many school psychologists contribute to make them logical liaisons between schools and medical/rehabilitation facilities. Many school psychologists are knowledgeable about clinical and medical issues and have served as transition facilitator for children who have been hospitalized for psychiatric reasons. School psychologists who have developed expertise about TBI may also serve the transition process by providing inservice presentations for school personnel. Blosser and DePompei (1991) developed objectives and identified topics suitable for professional training and development programs for educators. General topics they designated as appropriate for such programs include identification of the nature of TBI; similarities and differences between students with TBI and other types of handicapping conditions; the impact of impairments resulting from TBI on the student's learning and performance; program decision making, including policy and administration; educational program development including assessment and management strategies; and consultation and collaboration between professionals (rehabilitation and education) and with families for effective program planning.

Another problem facing educators who plan for the return to school of a child with TBI is the fact that the medical designations of mild, moderate, and severe used to classify degree of physiological disruption often do not provide information useful in predicting educational need. It often happens that a child who has sustained a mild injury is returned to school before sufficient time has elapsed and without the support services necessary for monitoring behavior and progress. Frequently, the educational performance of children who have returned to school following a TBI is hampered by subtle cognitive and behavioral problems (Savage, 1991). Cohen, Joyce, Rhoades, and Welks (1985) identified the following behavioral criteria necessary for a return to school:

1. Attend to a task for 10 to 15 minutes.

2. Tolerate 20 to 30 minutes of general classroom stimulation.

3. Function within a group of two or more students.

4. Follow simple directions.

5. Engage in some type of meaningful communication.

6. Give evidence of learning potential.

These criteria should be viewed as guidelines only and interpreted in a manner flexible enough to effectively accommodate individual differences among children. Based on classroom observation and other sources of information the school psychologist could help establish individually appropriate entry-level criteria.

An important component of the transition process is the development of an Individualized Education Plan (IEP) that will determine the child's educational program after the return to school. Although not appropriate for every child with a disability, the "one-size-fits-all" IEP commonly developed for children with learning disabilities is especially inappropriate for children with TBI. Brain injury affects each child differently. Some children will be only mildly affected and need only minimal services. Other, more seriously affected children, however, will need more services and a more restrictive environment. And many children with TBI will need related services such as speech-language therapy or occupational therapy. Therefore, input from the complete multidisciplinary team is important in IEP development.

A key concept in the IEP development for a child with TBI is flexibility. Students with TBI often make rapid progress in the first few months following their injury. Future performance levels often are not consistent with nor can they be inferred from current levels of performance. Because the student's needs may change rapidly during the early stages of the recovery process, the recommendation has been made (e.g., Savage, 1991; Ylvisaker et al., 1991) that the initial IEP should be written for a shorter period of time, namely 6 to 8 weeks, rather than the more customary 1-year period. Because TBI often affects more than academic functioning, it is important that IEPs contain provisions for addressing the child's other needs as well. The IEP must view academic progress as a part of the process of achieving independent functioning and should include provisions to foster the development of adaptive and effective behaviors that will enable the child to meet with educational, social, and vocational success (Roth et al., 1993).

Ylvisaker et al. (1991) recommended that the IEP contain a "package" of services including as much regular education as possible and supported by an appropriate combination of resource room assistance, remedial programs, tutoring, classroom consultation, related services, and possible outpatient therapy. Ylvisaker et al. (1991) also assert that the unique characteristics and possible rapid recovery of children with TBI make the ongoing success of their educational programs dependent on careful case management. The responsibility of the manager would be to monitor the program, make recommendations for change, and ensure that all staff are properly oriented to the child and program. Oftentimes well-conceived programs can deteriorate and cease to be appropriate without careful monitoring and management.

Just as the "one-size-fits-all" IEP is inappropriate for children with TBI, the "one-educational-placement-suits-all" is also inappropriate. The wide variety of outcomes subsequent to TBI mandates that educators consider the complete continuum of services as they plan educational programs for children with TBI. Educators also need to be flexible enough to allow for changes in placement as the recovery process progresses. Two areas in which flexible programming can be important include length of school day and length of time in a "regular" education classroom. Many children with TBI become fatigued easily; for many of these children a gradual return to a complete school day might be more appropriate than an abrupt reentry. In addition, as children recover they will need less restrictive educational environments and will be able to spend more time in "regular" classrooms. Systematic assessment and careful monitoring are essential to ensure that these changes are made in a timely and appropriate manner.

Although teaching methods and techniques uniquely beneficial for children with TBI have not been identified and educators are left to assume that sound teaching practices have the same chance of success for children with TBI as they do for other children with disabilities (Cruikshank, Bentzen, Ratzeburg, & Tannhauser, 1961; Heward & Oriansky, 1980), systemic factors do exist that can contribute to or detract from the quality of an educational placement once it has been made. Telzrow (1987) identified several characteristics of quality educational delivery systems for children who have sustained a TBI. Basing her assertions on successful rehabilitation programs, she suggested that school programs, at least initially, be provided in a self-contained classroom in which stress can be reduced by ensuring that adults, expectations, and the surroundings remain constant. In addition, she asserts that the need of the student with TBI for individual instruction and direct personal feedback mandates a low pupil-teacher ratio.

Brain injury impairs the capacity for learning. For this reason, a need exists to modify instructional program delivery and content as well as setting. Telzrow (1987) advocates that these programs be repetitive, provide for practice, and allow more time for learning to take place. Reducing time devoted to noninstructional activities is one method for achieving this end. The self-contained environment just described and an IEP provision for an extended school year can also allow more opportunities for repetition and practice. Telzrow (1987) also recommends that educational programs for children who have sustained TBI focus on learning process as well as academic content. Efforts to increase sustained attention, develop and follow a plan of study, and utilize memory clues were offered as examples of processes that might be incorporated into an educational program for children with TBI. Educational programs based on behavioral instructional strategies also appear to be most successful. Task analysis and systematic progression from goal to goal are key components to successful programs.

Because many children who have sustained TBI require related services as well as modified instruction, an integrated program that provides coordinated instructional and therapeutic services is viewed as preferable to a more segregated approach. One

1034

method of ensuring this integrated approach is to deliver related services in the primary instructional setting rather than via a "pull-out" design. According to Telzrow (1987) successful programs for children with TBI foster transfer of skills from setting to setting by providing opportunities to practice through simulation experiences. Utilization of the learning principles of cuing and fading is also recommended as beneficial for students with TBI, as is providing shadowing experiences for the student. Shadowing is a technique whereby the child is provided close and direct supervision during early trials at displaying a skill or participating in an activity. Because children who have sustained TBI often exhibit behavioral and emotional problems such as anxiety, depression, and/or acting out, the need to incorporate readjustment counseling into a child's program may exist. Finally, Telzrow (1987) recommends that because TBI can have a major impact on the family as well as the child, a formal system of communication between family members and school personnel should also be a part of an educational program for a child with TBI.

Programming for Behavioral and Emotional Needs

Post-traumatic cognitive difficulties can interfere with social as well as academic adjustment. Moreover, head injured children may lack the confidence to participate in social situations (Newton & Johnson, 1986). As previously described, a complete package of integrated related services can be an important part of a child's educational program. School psychologists may, therefore, be called upon to provide behavior management consultation or direct counseling as a part of the intervention package for children who have sustained TBI. Although each person who has incurred TBI displays a unique constellation of behaviors, enough commonality exists for Deaton (1990) to categorize behavioral deficits following TBI as problems in self-care, cognitive functioning (e.g., attention problems, impulsiveness), and interpersonal behaviors. Problems of behavioral generalization may also be apparent in these children and direct and explicit behavioral directives may be necessary for them to function in a school setting (Begali, 1987). Moreover, intrinsic reward and/or motivation is often insufficient in the head-injured population, and external reinforcement systems such as token economies may be necessary (Begali, 1987). In addition to positive reinforcement systems, timeout has proven particularly effective for disruptive and dangerous behavior exhibited by children with TBI (Newcombe, 1981). Begali (1987) adapted for use in schools Olson's general strategies for managing the behavior of head-injured clients. These guidelines and strategies include

- Promoting communication among staff.
- Permitting students to experience the logical consequences of their actions.
- Breaking long-range goals down into smaller steps.
- Providing clear and direct feedback.
- Serving as a role model of appropriate behavior.
- Manipulating the environment in order to reduce stress.
- Redirecting perseverative and organically based behaviors.
- Expecting variable performance from TBI students.
- Setting reasonable expectations.
- Involving the family in the behavioral plan (Begali, 1987).

In addition to the provision of indirect, behavioral consultation services, school psychologists may need to provide direct psychotherapeutic services to the student with TBI. A theme that runs through much of the literature dealing with psychoemotional issues surrounding TBI is "loss." The person recovering from a traumatic injury to the brain is, in many ways, different from the person who sustained the injury. Children who have sustained this type of injury may have particular difficulty adjusting to this circumstance because outwardly they may appear to be perfectly normal. A major goal of school psychologists and others who counsel children with TBI should be to help the individual accept the trauma, its consequence, and the new set of circumstances posed by the injury. Prigitano and Klonoff (1990) recommend a psychoeducational model that presents and explains clients' behavior in precise and concise units. Such a model provides not only information to clients, but also a framework in which to interpret behavior. Groups, if possible to establish, may be especially appropriate mechanisms for providing support and realistic feedback to students with TBI.

Working with Families

The changes caused by TBI in an individual's functioning extend their impact to other people with whom that individual interacts. Nowhere is this more obvious than within the family. The impact of TBI on the family, although often considered to be outside the purview of school psychologists, should be taken into account because the family is such an important part of any child's life and because their support and cooperation are essential for the child's success in school.

A family's response to the knowledge that a child has sustained a TBI has been likened to the classic bereavement reaction (Hall, 1989; Martin, 1990) through which family members progress through stages of grief on the way to an acceptance of the circumstance. Although a complete discussion of these stages is beyond the scope of this chapter, a brief description follows. Initial reaction to the accident is one of shock. Parents are often disoriented, may experience feelings of helplessness, and may have difficulty thinking rationally. After the initial shock subsides, parents often shift into a phase of denial that may last for months. Although Hall (1989) warns against attempts to destroy this protective mechanism, professionals should also guard against giving a falsely optimistic prognosis and be aware that persistent denial may drive parents to constantly search for treatments that they unrealistically believe could totally reverse the brain injury.

As parents come to grips with the reality of the situation, they may respond with a profound sense of sorrow. The grief or mourning reaction for a child with TBI has been likened to the grief that is experienced upon the birth of a child with severe disabilities: Both situations entail a loss and the substitution of an earlier perception of the child with another, less pleasant one. Oftentimes commingled with feelings of sorrow is a diffuse sense of anger at the injustice of the child's condition. It is not unusual for some of the anger to be turned inward; parents often experience feelings of guilt associated with the child's accident.

Finally parents reach a stage of acceptance and accommodation and begin to be able to deal with the child of present reality rather than the child as he/she was before the trauma. This process of coming to terms with the child's condition is not a one-time occurrence — it is often interrupted by fresh episodes of grief and anxiety. Although these generalizations have been proffered to help the professional formulate a response to the family that has experienced TBI, it is important to remember that they are generalizations and the reality of the situation for a particular family may be much more complex and variable.

In addition to leaving a child with diminished abilities and perhaps a different personality, severe TBI can affect the family in a variety of other ways as well. Children, who require long-term rehabilitation present their families with a different set of responsibilities and demands. The amount of time and energy expended simply transporting the child can be daunting as can the new and extra demands for home care presented by the child. Another source of stress for the parents of a child severely disabled by a head injury is the realization that their responsibility for the child will be ongoing and continue much longer than previously expected. The financial strain of providing for the needs of the child can also be a source of substantial stress. The new circumstances of the family of a child who has sustained a TBI often result in at least some social problems involving isolation, loss of emotional support, and restricted independence (Lezak, 1988).

In addition to the stresses and strains encountered by the parents of the child with TBI, specific problems are also associated with the child's siblings. Two common results of TBI for the uninjured sibling are a decrease in parental attention and an increase in responsibility. In addition, increased demands at home may prevent siblings and/or parents from participating in typical activities, therefore decreasing social contacts and support. Siblings often experience feelings of confusion, anger, shame, and guilt as a result of these changes in family roles and relationships.

School psychologists can assist families with their adjustment in several ways. Listening carefully and providing an empathic ear can provide an important service to family members. Oftentimes professionals are so intent on conveying information and directions that they do not take the time to listen to the concerns of the parents. A sensitivity to the parents' current stage in the bereavement process can lead the school psychologist to tailor his or her presentation according to the parent's needs at the time. For example, parents still in a state of shock may need information to be presented in small amounts and on more than one occasion. On the other hand, parents experiencing great sorrow at their child's condition may need assistance dealing with feelings of guilt. Because the personal and financial demands of caring for a child who has sustained a severe head injury can be so draining, school psychologists can help by providing information regarding respite care services as well as rehabilitation facilities that operate with sliding payment schedules or in other ways that could ease the families' financial burden. Hall (1989) offered suggestions that are helpful in working with parents of children who have incurred a TBI. These include giving important news to both parents simultaneously; providing a quiet, distraction-free environment for discussion; allowing ample time for questions; and encouraging parents to bring another adult for support and to reinforce the information provided by the professional.

Their location in the schools and subsequent availability to children provide school psychologists with a unique opportunity to help siblings adjust to their new family circumstances. Serving as a source of information about TBI and its effects can be helpful to many siblings. Others may experience greater adjustment difficulties and require therapeutic intervention. Group counseling may be a particularly effective method of providing support, but the low incidence of TBI may make the establishment of a group difficult.

SUMMARY

The two concepts that are probably central to effective service to children who have sustained traumatic brain injury are variability and flexibility. Children sustain TBI in any number of ways; the effects on the child's physical, cognitive, and behavioral functioning are completely idiosyncratic; the child's level of functioning can change from one day to the next; and the school and home environments to which children must return following a head injury vary widely. In order to effectively serve this population, school psychologists and other professionals must be aware of this variability and realize that TBI impacts each child and family in a different manner. Although some generalizations can be made and guidelines offered, flexibility must be a key principle guiding intervention efforts; effective service can be provided only by tailoring the efforts of the professional to the needs of the individual. Despite the fact that the need for flexibility is important when working with all children, it is especially important when working with children with TBI because of the variability of needs among the population and the rapidity with which their functioning levels can change.

Another concept important in working with children with TBI is multidisciplinary coordination. Because TBI can affect all aspects of children's functioning and development, effective services can only result from the coordinated efforts of representatives of different disciplines. Coordinating these services can require much effort, but the unique needs of these children can only be met if the expertise of educators and allied professionals is incorporated into the educational program.

School psychologists can play key roles in providing appropriate educational services to these children. One important function that the school psychologist can perform is to ensure that broad-based, comprehensive, and timely assessment provides a valid picture of the child's assets and deficits that can be incorporated into an appropriate educational plan. School psychologists can also serve the population with TBI by providing inservice presentations to teachers and other educators about the nature of the disability and the needs of the children. Providing ongoing consultation to teachers to help them effectively meet the educational and behavioral needs of these children is another important service that the school psychologist can render. Direct intervention in the form of counseling to help the child with TBI to come to terms with the disability may also be necessary. Finally, school psychologists need to be sensitive to the effects that TBI can have on the family and provide support for parents and siblings.

AUTHOR NOTE

The impetus behind this chapter was a best-practice document created for the Illinois School Psychologists Association. That document was written by a committee chaired by Gloria Roth and included Richard Harley, Jennie Probat, Joe Vaal, and myself. I thank Steven Shaw of Illinois State University for sharing his expertise as I prepared this manuscript.

ANNOTATED BIBLIOGRAPHY

DePompei, R., & Blosser, J. L. (Eds.). (1991). School reentry following head injury [Special issue]. *Journal of Head Trauma Rehabilitation, 6*(1).

Provides articles relating to many issues associated with the reintegration of children with TBI into a public school setting. Of particular use to school-based professionals are a checklist of activities to ensure that a successful transition takes place and an outline useful as an aid in developing an inservice program regarding the educational needs of the child with TBI.

Begali, V. (1987). *Head injury and adolescents: A resource and review for school and allied professions*. Brandon, VT: Clinical Psychology Publishing Co.

A good overview of brain injury and its effects on children. Provides chapters concerning basic brain functions, mechanisms of brain injury, sequelae of brain injury, assessment of children with TBI, and treatment rationale and strategies for educational settings.

Bigler, E. D. (Ed.). *Traumatic brain injury: Mechanisms of damage, assessment, intervention, and outcome*. Austin, Tx: Pro-Ed.

The subtitle explicitly states the sections of this edited volume. Although many of the topics of discussion are similar to the Begali book described above, the presentation is more detailed and technical. Early chapters provide excellent photographs of CT scans and actual brains that depict effects of brain injury.

Savage, R. C., & Wolcott, G. F. (Eds.). (1988). *An educator's manual: What educators need to know about students with traumatic brain injury*. Southborough, MA: National Head Injury Foundation.

As the title states, this volume was created specifically for educators. It contains valuable information written in a style that can be understood by readers who possess little prior knowledge of the topic. Two useful components of this volume are a glossary worthwhile for educators unfamiliar with the medical terminology associated with TBI and a list of state head injury associations valuable for those wishing to become more involved or network with other professionals.

Best Practices in Gifted Education

Teresa Argo Boatman
Keith G. Davis
Camilla P. Benbow
Iowa State University

OVERVIEW

Providing educational programming that meets the academic and intellectual needs of gifted and talented students is a challenging task facing educators throughout the nation. With the increasing emphasis on serving children in the least restrictive environment and prereferral interventions, educators are charged with the task of serving increasingly heterogeneous classrooms. The changing roles of school psychologists, as evidenced by the focus of this volume, is moving away from its traditional roots of classification and toward an expanding role of problem solving in the general education classroom. School psychologists, more than ever before, find themselves involved with students at all points along the continuum of academic behaviors. Highly able students, commonly referred to in the school as talented and gifted (TAG), are a traditionally underserved population but may benefit greatly by the new problem-solving focus in education.

As school psychologists embrace the role of assessing and meeting the individual needs of students, problems may be conceptualized as discrepancies between the student's performance and the expectations of the educational environment (Tindal, Wesson, Deno, Germann, & Mirkin, 1985). This discrepancy may result from a student's performance or skill deficit or from inappropriate demands of the environment. Frequently, the successful resolution of the problem requires the consideration of both student and environmental factors. A fourth-grade student with severe reading difficulties provides a useful illustration. Not only is the student deficient in the requisite skills to function in the fourth-grade reading curriculum, but that curriculum level may be inadequate to remediate those skills. This student's deficit in basic reading skills may be more effectively remediated by instruction at the third- or second-grade level.

This example illustrates a principle that guides much of curriculum and teaching and is referred to by cognitive developmental psychologists as the moderate-discrepancy hypothesis (Siegler, 1991). Simply, learning is most effectively promoted when the child is presented material slightly more difficult than the child's current level of functioning. Thus, the second- or third-grade curriculum may be the appropriate academic placement and permit his reading skills to remediate without being overwhelmed by the demands of the fourth-grade curriculum for which he is not prepared. A parallel is the case of a highly able student functioning significantly beyond the level of her peers. Rather than receiving instruction in grade level materials, which she has previously mastered, her needs may be more appropriately met by instruction in curriculum moderately beyond her current level of mastery. Herein lies the "problem" that a problem-solving approach addresses in gifted education — serving the needs of gifted students through educational placements that address their special academic needs.

The role of gifted education in today's schools should be to identify the specific talents and abilities of gifted students and nourish those abilities through placing students in appropriate curricula. The challenge to school psychologists is to advocate for the identification of these individual needs of gifted students and the provision of effective interventions. To aid school psychologists in their challenge, this chapter's authors present an approach to assessment, intervention, and evaluation that integrates the best practices in the field of gifted education. The primary emphasis is toward appropriately identifying the specific patterns of abilities of each student and then providing educational placement based upon the specific abilities (not the chronological age) of each student. The process parallels the problem-solving approach used by school psychologists in working with developmentally challenged students, students who are usually the outliers in the classroom. Gifted students are also outliers distinguished from developmentally challenged students by their place at the opposite extreme of the developmental continuum. The school psychologist's role is similar with students at both ends of this continuum; only the interventions differ.

Definition of Giftedness

Among researchers interested in intellectual abilities, a framework that has received a remarkable degree of acceptance (cf. Lubinski & Dawis, 1992), is that cognitive abilities are organized around two dimensions. The first is the sophistication of the intellectual repertoire, commonly referred to as general intelligence. The second dimension is the content of the abilities, which are divided into three distinct factors: verbal/linguistic, numerical/quantitative, and spatial/pictorial. Giftedness, therefore, can be identified in verbal, numerical, and spatial abilities.

Considerable effort has been made to define and refine the construct of giftedness further. There is a general agreement within the field of gifted education that giftedness arises out of a mixture of advanced cognitive abilities, personality traits, and environmental circumstances (Feldhusen, 1986; Tannenbaum, 1983). Feldhusen, for example, identified giftedness as a composite of four general characteristics: general intellectual ability, which is characterized by higher order cognitive processes accessed in problem solving; specific talents such as verbal or mathematical ability, which may be based on curriculum demands; a self-concept of being competent and capable of new ideas, inventions, and performances; and motivation characterized by an achievement orientation.

Yet, within the school system, intellectual abilities have been more narrowly defined and traditionally identified via outstanding performance on national achievement tests, such as the Iowa Test of Basic Skills or the Iowa Test of Educational Development. Gifted programs typically set an inclusionary criterion of students scoring in the top three to ten percent of ability on these standardized tests of achievement. General measures of intelligence (e.g., the Weschler Intelligence Scale for Children–III) were used in the past and tended to define giftedness as two standard deviations above the mean (> 130 IQ). General intelligence measures, such as the WISC–III, are not used as frequently in school gifted programs today, however, due to the lower cost and availability of other assessment alternatives, the expanded view of giftedness, and the less clear applications of such scores with educational programming. One of the drawbacks of the standardized tests of achievement and the structure of the school system is that only two of the three content areas of cognitive abilities, the verbal/linguistic and numerical/quantitative, are adequately assessed. The spatial/pictorial content area is all but ignored within the current school system.

Within the school system, it is imperative to develop an operational definition of giftedness. The boundaries of the operational definition provide guidelines for making programming and administrative decisions and channeling resources. This chapter's operational definition is based on the one used by the 20-year-old Study of Mathematically Precocious Youth (SMPY) research program at Iowa State University and focuses upon the academic components of high ability. A child who shows exceptional ability within a specific talent area is identified as gifted within that area. While the authors recognize the poignant needs of children with talents in other areas, this chapter is restricted primarily to academic talents which can and should be served reasonably in the schools. Attention is concentrated especially upon the quantitative reasoning and verbal reasoning abilities as those two areas may be objectively, reliably, and validly measured within the school setting. Additionally, appropriate educational interventions have been demonstrated to strongly influence future performance in these areas.

School Psychologists' Role

As school psychologists utilize effective models of systematic problem solving, they encounter increasing opportunities to effect change in gifted education. Through consultation with teachers, parents, and administrators, school psychologists assist in the identification and interpretation of exceptional academic talent in young people, identify interventions that address the needs of the gifted learner, and help evaluate the effectiveness of these interventions for individual students. Serving the student, often indirectly through consultation, the psychologist advocates the utilization of best practices outlined in the research. The information provided herein, coupled with the school psychologist's knowledge of psychometrics and problem solving, should begin to provide the foundation for these consultation services.

The school psychologist as a consumer of research on gifted education will generally be led outside of the school psychology professional journals. This chapter's inclusion in this volume represents a growing trend in the field to serve all students who may require special curricular modifications through the problem-solving approach. As this trend continues and school psychologists become more involved in serving this population, additional research on the gifted will make its way into the professional school psychology journals. The annotated bibliography at the end of this chapter should provide an excellent resource for further research in appropriate educational options. In addition, four journals, *Gifted Child Quarterly*, *Journal for Educating the Gifted*, *Gifted Child Today*, and *Roeper Review* will provide current and relevant information for school psychologists interested in gifted education.

BASIC CONSIDERATIONS

Educational programming for talented and gifted children is currently driven by three educational models: acceleration, ability grouping, and enrichment (Feldhusen, 1989). Considerable research within the field of gifted education has been devoted to developing and implementing these models as well as evaluating their effectiveness in serving the needs of gifted students. As the academic needs of highly able students become more fully understood, it becomes clear that no one form of programming addresses the needs of all talented and gifted students. The following section highlights the basic components of acceleration, ability grouping, and enrichment to provide the school psychologist a framework of the educational options available in the schools.

Acceleration

Although acceleration has been used since the one-room school house as a means to meet the academic needs of advanced students, the true meaning of acceleration is often misunderstood. Some educators wrongly conclude that acceleration consists only of radical jumps from one grade to another. Acceleration, however, encompasses a much wider range of educational alternatives than just grade skipping. The goal of acceleration is curricular flexibility or curricular access without regard to age. Rather than subjecting a student to a lock-step approach, the curriculum can be modified for the purpose of meeting the individual needs of a student. Some of the accelerative educational options are

- Early admittance to school.
- Subject-matter acceleration.
- Grade skipping.
- Early entrance to college with or without a high school diploma.
- An International Baccalaureate.
- Course enrollment one or two years earlier than typical.
- Enrollment in college courses while still in high school.
- Curriculum compacting.
- Advanced Placement (AP) courses.

See Figure 1 for descriptions of these options, all of which are designed to provide an academic curriculum commensurate with individual ability and achievement levels. A definition encompassing this concept of acceleration was outlined by Feldhusen (1989) as "the process is really one of bringing gifted and talented youth up to a suitable level of instruction commensurate with their achievement levels and readiness so that they are properly challenged to learn new material" (p. 8). Acceleration, therefore, provides the student the opportunity to utilize the standard curriculum at a pace and time that is appropriate for his/her ability level.

Interventions used when working with gifted students are highly focused upon accelerative opportunities, primarily because acceleration provides both short- and long-term benefits for academic performance. Additionally, research studies for over 60 years have identified acceleration as best practice for gifted students (Benbow, 1991; Benbow & Stanley, 1983; Feldhusen, 1989). Reviews of research on acceleration have shown that early entrants were at a comparable level as their classmates or had surpassed them (Proctor, Black, & Feldhusen, 1986) and that accelerated talented youngsters performed as well as talented, older pupils (Kulik & Kulik, 1984). Accelerated students also tend to earn high grades and win honors at the collegiate level (Swiatek & Benbow, 1992). The culmination of this research is that accelerative options have consistently proven to be the most effective intervention with highly talented youth. Further, accelerative options are economical, generally utilizing resources already available in the school.

A commonly held myth concerning acceleration is that the social and emotional development of the gifted child is affected adversely by accelerative options. Contrary to this belief, research indicates that acceleration is not detrimental and may even have some positive effects on social and emotional development. At different ages in their development, accelerants have been shown to be well-adjusted in comparison with same age counterparts (Robinson & Janos, 1986), report high self-esteem and internal locus of control (Richardson & Benbow, 1990), and exhibit advanced social maturity (Janos & Robinson, 1985). In all, there is not one empirical investigation that shows harmful effects of acceleration on social and emotional development, with no group of talented students at particular risk either (Swiatek & Benbow, 1992).

Ability Grouping

The second most effective educational intervention with gifted students is ability grouping. Students are grouped according to current level of mastery, ability, and/or achievement for the purpose of reducing the heterogeneity of the group and increasing the appropriateness of the instruction. Despite its utility, this intervention is frequently rejected as a viable educational option, often being misconstrued as conflicting with the special education goals of mainstreaming and least restrictive environments. These special education goals are important and, as illustrated throughout this volume, are directly tied to best practice and mandated by public law. However, the grouping eschewed by these goals is *disability*

FIGURE 1. Curricular flexibility options for gifted students.

The following educational options and score criteria were developed for junior high age students who have completed the ACT or SAT. The score criteria act as a guideline for educational planning. Additional factors such as student motivation, access to resources, and academic maturity should be taken into consideration.

SAT–Verbal	200–470	SAT–Verbal	430–480
SAT–Math	200–550	SAT–Math	520–800
ACT–English	0–23	ACT–English	21–36
ACT–Reading	0–23	ACT–Reading	23–36
ACT_Math	0–19	ACT–Math	18–36
ACT–Science Reasoning	0–25	ACT–Science Reasoning	23–36
ACT–Composite	0–22	ACT–Composite	21–36

Seventh-grade students scoring in this range may want to consider options for their educational plans.

1. *Enriching learning opportunities from a variety of areas.* Develop independent research projects, potentially with specific contests or competitions in mind. Students may attend a summer course in an area of interest or attend a lecture series at a local science center, art museum, or college.

2. *Early course entry.* Algebra I in the seventh or eighth grade or the intense study of a foreign language in junior high or elementary school. All course sequences should be continuous, without obvious breaks in sequency.

3. *Access to Advanced Placement (AP) and Honors courses.* AP and Honors courses may provide the appropriate level of educational challenges to gifted students. If AP courses are not offered in the local school, the option of preparing for and taking the AP exams is still available.

4. *Mentoring program.* Specific interests and abilities can be developed with assistance from an outstanding adult in that field. For example, students who excel in the social sciences may be paired with a professor completing research in that area.

5. *Involvement in contests and competitions.* Group and individual contests such as Science Bowl, MathCounts, Physics Olympiad, and History Day provide a community of peers with whom gifted students may choose to interact.

Seventh- and eighth-grade students scoring in this higher range may consider suggestions 1 through 5 with the following options.

6. *Self-paced instruction.* Current areas of strength in a subject can be identified and tested. Once areas of mastery have been identified, students should proceed through the remaining course work at the rate appropriate for the individual student.

7. *Attendance at summer academic programs.* Many summer courses offer an opportunity for students to complete a semester or year's worth of academic material in a 3- or 4-week time span, for which they may receive credit in their local school.

8. *Course skipping.* Students can be moved into courses appropriate for their level of academic ability and mastery. For example, a sixth-grade mathematically gifted child may take pre-algebra to prepare him or her for algebra in the seventh grade.

9. *Grade skipping.* This works best when it incorporates a natural break (e.g., skipping the last year of middle school by oing directly to high school). Grade skipping is reserved for those students who are achieving highly in all areas of the curriculum.

10. *Course compacting.* The completion of a course in a shorter amount of time may be accomplished by self-instruction or mentoring of the student.

11. *Early entrance to college.* Gifted students may consider leaving high school and attending college following the sophomore or junior year of high school.

grouping — not ability grouping. Grouping students by disabilities, which are unrelated to their educational needs, is truly a travesty. In contrast to grouping by disability, ability grouping strives to identify educationally critical characteristics such as current level of mastery, ability, and achievement, thereby increasing the appropriateness of instruction for the students grouped.

Ability grouping is commonly divided into two forms: within class and between class. For within-class groups flexible, independently paced instruction is offered for each student or student assignments based on ability level for specific curriculum. An example of within-class grouping is commonly seen in the divided reading curriculum at the elementary level. Between-class groups may be special classes assigned by ability level, subject-matter grouping across grade lines according to ability level, or flexible grouping according to performance rather than age. An example of between-class ability grouping is the precalculus mathematics series offered at the secondary level. The grouping of these students is related to their mastery of the earlier components in the series. The purpose of ability grouping is to provide students at a similar level of mastery, ability, and/or achievement educational instruction that is an optimal fit to their needs.

The meta-analysis research on the efficacy of ability grouping with gifted students has pointed to clear and consistent benefits (Kulik & Kulik, 1991; 1992). The benefits are most positive when grouping is accompanied by curriculum modification. Students who were grouped and then exposed to enriched or accelerative learning environments show moderate-to-large positive academic gains from grouping. A cross-grade grouping or within-class grouping that included curriculum matched to the group ability showed small positive effects in academic gains. Students who were exposed to multilevel grouping that included few planned adjustments to curriculum showed little academic gain (Kulik & Kulik, 1992). This evidence leads us to the same conclusion as Feldhusen and Moon (1992), who state that "the linkage among grouping, acceleration, and differentiated curriculum is an essential aspect of the instructional services that produces higher achievement among gifted and/or high-ability students" (p. 65).

Opponents of grouping purport that removing high-ability learners from the classroom will deprive the average-ability students of important positive academic role models. Shunk (1987) found that students tend to choose role models who are at their same ability level. Thus, the removal of the high ability students does not affect role model selection and may actually provide for an increase in positive role modeling among like-ability students. Despite the benefits of ability grouping, it tends to be the most infrequently used intervention in schools. This may be due to problems of allocating the additional resources needed for ability grouping or simply due to the misunderstandings associated with this intervention.

Enrichment

The concept of enrichment within the school setting not only has been misunderstood but also is troubled by inconsistency in definition (Treffinger, Callahan, & Vaughn, 1991). Broadly defined, enrichment includes any activity outside the regular curriculum that provides a richer and more varied educational experience. A wide range of educational activities, including field trips, independent research projects, artistic creations, science fair projects, and cultural experiences are categorized as enrichment. Most enrichment interventions are aimed at providing an avenue within a total school program to develop creative-thinking skills and problem-solving ability or to nurture talents and interests in an effort to build a foundation for more developed enrichment activities for advanced students (Renzulli & Reis, 1985). Most enrichment activities tend to occur in the "resource room," where gifted students have been pulled out of the regular classroom for one or two hours per week. Pull-out is the most frequently used mechanism to serve gifted students in the United States.

It is critical that enrichment activities are carefully planned so as to avoid becoming just simply fun and games. There are numerous models and programs of enrichment that have been outlined (e.g., Renzulli, 1986). Renzulli and Reis's *Schoolwide Enrichment Model* (SEM; Renzulli & Reis, 1985) will be highlighted here to represent the specific components of an enrichment program because it is an extremely popular model in today's schools. SEM provides enrichment to a broad spectrum of students with a focus on providing creative productivity and integrating gifted education into the regular classroom. Three different types of enrichment are provided, each successively more challenging and integrative in nature. Type I activities provide general exploration of topics not available in the regular curriculum. Type II activities provide the tools for further learning by promoting thinking and feeling processes as well as enhancing general skills in creative thinking, skill usage, and use of reference materials. Type III activities provide practice in thinking, feeling, and acting like a professional and focus upon promoting advanced understanding of the content and process integral to the development of an authentic product through an in-depth investigation on a topic of choice. The SEM model suggests using curriculum compacting, an accelerative option through which teachers help students master the regular curriculum in a more economical and efficient manner, to enable students to use their additional educational time for enrichment activities.

Enrichment programs have been widely embraced by many school systems as the primary intervention to meet the needs of the gifted child. The overall results of Treffinger, Callahan, and Vaughn's (1991) comprehensive review of the limited literature indicated that enrichment program students achieve as well as peers and sometimes better than control groups. In addition, enrichment programs are effective in reaching program goals, parents and students have very positive attitudes toward enrichment activities, and participation in enrichment programs do not have an adverse effect on self-confidence. The overall conclusion of the review, however, indicated "a paucity of systematic, experimental research on the effectiveness, and particularly long term effectiveness, of enrichment efforts" (p. 40).

The school psychologist should remember, however, that within an individual school district, maximum benefit is achieved when appropriate components from each of the instructional theories are integrated into an individual educational plan.

BEST PRACTICES

Best practices of working with gifted children do not differ significantly from those used with other special needs students. A problem-solving model, in which the identification of educational needs of the student, development of an individual educational plan, access to educational opportunities within the school, and evaluation of the effectiveness of the individual educational plan provides a conceptual approach to working with gifted children and educators. A combination of acceleration, ability grouping, and enrichment practices, in which the appropriate options for the individual student are integrated as necessary, provide the best intervention options.

An understanding of best practices in gifted education may be illustrated by looking retrospectively at the educational placement decisions that could have been made for one young man, Jeffrey, given unlimited allocation of resources, support, and access to curricular options. It should be noted that this example combines a large number of potential interventions to provide illustration of the processes of integrating acceleration, ability grouping, and enrichment options. For each student, the configuration of instructional activities that provides the framework for the most appropriate individual educational plan will depend upon two components: a thorough evaluation of the individual student's current level of mastery, abilities, preferences, and motivation and a degree of creativity utilizing options available within the school district and community.

Jeffrey first came to our attention as a 10-year-old sixth-grade student at a local elementary school. When he was in the second grade, Jeffrey's school had identified him as gifted. Prior to beginning formal education, Jeffrey could complete mathematical calculations (subtraction and addition) and was interested in drawing maps that were proportionally correct. When we met Jeffrey, he was attending weekly astronomy lectures at the local university with his father and expressed interest in several other areas of the sciences as well as mathematics. Jeffrey enjoyed studying languages and had completed short, introductory courses in Spanish and German. His test scores in all subjects were superior; however, his grades were only average. The teachers reported that Jeffrey would commonly fail to turn in assignments or turn in incomplete assignments. It was obvious, however, that Jeffrey was not a mediocre student. Jeffrey's parents and teachers, as well as Jeffrey, were seeking answers. At what level was Jeffrey functioning intellectually? What curriculum would best challenge his abilities? Where would they find the educational challenges that would best meet his needs? So began the search for best practices in gifted education that would answer these and other questions.

Identification of Needs

As with all problem-solving approaches, the identification phase is the most important, as it lays the groundwork for the educational interventions that follow. Identifying the academic needs of a gifted and talented child is a three-phase process: identifying abilities, assessing interests, and identifying suitable academic placement.

Assessment of abilities. The annual or bi-annual nationally standardized tests, such as the Iowa Test of Basic Skills (ITBS) and the Iowa Test of Educational Development (ITED), are good measures of overall level of performance within subject matter. These tests provide a mechanism of tracking student progress as well as serving as an initial screening tool for students who may be at the lower or higher end of the continuum of academic ability. Traditionally, students who score at or above the 97th percentile on nationally standardized tests are considered intellectually highly able. These tests, however, provide little information concerning specific abilities of a gifted child. Students who score |c3\\fl||a1 97th percentile on age-appropriate standardized tests are affected by the ceiling effect of the test. That is, the test is not difficult enough to accurately assess the true ability level of individuals scoring in the upper percentiles. In addition, the results of standardized achievement tests are scores of broad range achievement, measuring how well the students have accomplished academic goals as compared to peers in a national normative sample. Tests of aptitude, especially out-of-level examinations, are better measures for gifted students of actual potential for achievement and will serve as better indicators of specific strengths and weaknesses.

When faced with the dilemma of further defining the academic abilities of gifted students, Dr. Julian C. Stanley at Johns Hopkins University developed the Talent Search model of identification. Through the Talent Search model, students who score in the top 3% on national standardized achievement tests (e.g., ITBS) are invited to take an out-of-level test. In the original Talent Search and its subsequent offshoots, junior high students are invited to take the College Board Scholastic Aptitude Test (SAT). The SAT provides a SAT-Verbal and SAT-Mathematics score and is designed to measure verbal and mathematical reasoning abilities. The SAT traditionally is a college entrance examination completed during the junior or senior year of high school. When completed at the junior high school age, however, the SAT has proved to be an especially appropriate measure of the specific verbal/linguistic and quantitative reasoning abilities of a gifted individual (Benbow & Wollins, in press; Benbow, 1991). Among students who are in the top 3% on the ITBS, the distribution of scores on the SAT range from 200 (chance) to 800 (the top score). The mean score for this select group of junior-high-age students is comparable to the national sample of high school students. The Talent Search model has been implemented across the nation and over 150,000 junior high school age students participate annually (VanTassel-Baska, in press). In addition to the SAT, the American College Testing Program (ACT) Assessment recently has been used by some talent searches. How useful this instrument will be in assessing the abilities of gifted students remains to be determined. Recently, the Talent Search model also has been implemented for fourth through sixth grade students through various centers for gifted students, using out-of-level tests originally designed for typical eighth-grade students.

Although research has shown that best practice for screening gifted students is through standardized tests, other methods of assessment may be necessary for traditionally underrepresented populations. Behavioral observation by the teacher, parents, and school psychologist may identify characteristics that are common to gifted students. Baldwin, Gear, and Locito (1978 in Baldwin, 1991) provided an extensive list of exceptional characteristics to look for in children who are culturally diverse, socioeconomically deprived, or geographically isolated. These characteristics include good memory, intuitive grasp of situations, understanding of compromise, tolerance for ambiguities, insight, inventiveness, flexibility, originality, ability to think systematically, uncluttered thinking, insightfulness, special aptitudes in the arts, and skilled body movements. Inclusion of teacher and peer nomination also expands the scope of identification to include students not selected through standardized examinations. Although these behaviors and nominations are not objective measures of a high academic ability, they may be used effectively to screen students for further and more valid assessment of abilities.

Assessment of interests. Identification of interest areas has not been traditionally integrated into developing educational plans for gifted students. However, at the other end of the continuum, interests have been a primary component of vocational rehabilitation programming. Extending the Theory of Work Adjustment (TWA) developed by Dawis and Lofquist (1984) to appropriate educational placement indicates the need to assess the personal preferences of gifted students. According to TWA, optimal educational and work environments are those in which the individual corresponds with the environment on two levels, *satisfactoriness* and satisfaction. Satisfactoriness is the correspondence between an individual's abilities and the ability requirements of the environment. Satisfaction is the correspondence between an individual's preferences and the types of reinforcers provided by an occupational or educational track. The extent to which satisfactoriness and satisfaction are achieved determines the eventual educational choice, degree of commitment to this choice, and the eventuality of whether talents have the opportunity to be brought to fruition (Benbow & Lubinski, in press). Therefore, the identification of the individual's preferences in addition to his ability level may be an important consideration in academic placement decisions.

Assessing areas of interest may be a formal or informal process. Formally, there are several tools available to most school guidance counselors. The student may complete a career planning session, which involves assessment instruments such as the Strong Vocational Interest Blank, the DISCOVER computer program, or other nationally recognized career guidance systems. These systems provide information concerning the degree to which the individual's interests and traits match the interest patterns of a particular occupation or college major. Informal interviews, where additional information concerning pastimes, hobbies, and individual pursuits may be gathered, provide further clues to specific interest areas. Interest and preference data may then be used to identify projects in enrichment activities, the focus of mentorship experiences, or as data in designing an educational plan.

Assessment of curriculum. The school psychologist's expertise in working with educators to make academic placement decisions may play an important role in identifying the appropriate curriculum for the gifted child. An assessment of the correspondence between the curriculum level and a student's achievement level may be completed through curriculum-based assessments, comparison of classroom achievement and out-of-level test results, and diagnostic testing. Curriculum Based Measurement (CBM), although not typically used with gifted children, provides an easily understandable measure of the level of curriculum most appropriate for an individual student. Marston and Magnusson (1988) use the CBM technology of survey-level assessment to determine the needs of elementary-age students. This procedure identifies children as two years discrepant when they test below the 16th percentile (i.e., one standard deviation below the mean) one grade below their current grade level. A similar discrepancy could be noted for the gifted student performing above the 84th percentile (one standard deviation above the mean) one grade above her or his current grade level. School psychologists well versed in CBM technology with access to local normative data may make good use of this method of assessment for identifying the appropriateness of the curriculum for individual students.

A comparison of the performance of the student on the out-of-level testing and placement in the school curriculum provides important diagnostic information. A sixth-grade student whose mathematical reasoning is at the level of a high school senior, as identified by the SAT-Math, but who is in the sixth-grade curriculum is not in a mathematics curriculum that is meeting her needs. The out-of-level test results provide guidance as to the possible mismatch between the child and the existing curriculum. Programming options generated from out-of-level testing are presented in Figure 2. Further assessment (see diagnostic testing following) would be warranted to effectively plan for this student's curricular placement. As with all educational decisions impacting individual children, the school psychologist will want to collect multiple forms of assessment data across multiple settings and observers and establish appropriate decisions with convergent assessment data and professional judgment.

Another avenue of identifying the appropriate academic curriculum for a child is to complete diagnostic testing within specific subject matter. Diagnostic tests designed by the instructor or nationally standardized examinations are administered at the beginning of each unit, quarter, or semester. These tests are designed to assess student knowledge of specific subject matter prior to the presentation of the corresponding curriculum. High ability students frequently master large portions of a curriculum independently before it is presented formally. Using diagnostic testing, student mastery of subcomponents of the subject matter is identified and students are then taught only those areas of the curriculum which they have not mastered. The SMPY math courses have successfully used this Diagnostic Testing followed by Prescriptive Instruction for almost 20 years (Benbow, 1986).

Let us return to Jeffrey. Jeffrey scored in the 99th percentile on the Iowa Test of Basic Skills. To provide more information concerning Jeffrey's specific strengths and weaknesses, he completed the SAT. He scored 600 on the SAT-Math and 280 on the SAT-Verbal. These scores placed him in the 89th and 8th percentiles, respectively, in comparison to college-bound high school seniors. Jeffrey's mathematical reasoning ability was well above that of most college-bound high school seniors, with his verbal reasoning ability not as well developed as his mathematical reasoning ability. The teacher diagnostically tested Jeffrey and noted mastery of pre-algebraic skills in mathematics, well beyond the sixth-grade curriculum. Criterion-referenced assessment in social studies and language usage indicated average performance for the sixth-grade curriculum. In addition, Jeffrey completed an informal interest survey indicating a strong preference for scientific and task-oriented activities as well as blossoming interests in languages and foreign cultures.

An educational team then had the data — Jeffrey's level of mathematical and verbal reasoning ability, an informal measure of his interests and preferences, teacher observations, and the appropriateness of the curriculum in meeting his needs — with which to make educational decisions.

Developing an Educational Plan

Utilizing the data gathered through the identification phase, the team developed an educational plan for the coming school year and beyond, utilizing the various educational options available through the regular curriculum, accelerative options, enrichment activities, and resources outside the school. The educational plan provides the optimal educational placement based upon the skills, level of academic performance, and preferences of the individual student as well as the resources of the school and the community. As a side note, school psychologists should be aware that a large proportion of money within gifted programs is allocated to enrichment activities. This intervention, however, is the least cost effective and has surprisingly little research support. As will be described shortly, curricular flexibility (acceleration) provides the optimal educational placement for gifted students with little need to create new curriculum or differential programming. Instead, curricular flexibility adapts existing curriculum to meet the needs of the gifted learner.

Educational plan components. The development of an educational plan is an evolutionary process. An initial plan outlines the appropriate curricular placement, independent study, summer academic experiences, enrichment options, and extracurricular experiences (band, newspaper staff, mentoring experiences, volleyball, etc.) for the next 1 to 6 years. On a yearly basis, the plan is reviewed to respond to a developing individual and to integrate new educational opportunities, assessment results, or interests of the child.

When considering educational opportunities for the gifted child, the accelerative options outlined in Figure 2 have been shown to be effective (Benbow, 1991). Acceleration, or curricular flexibility, involves utilizing the existing curriculum in the school system or local community college and placing the child at the curriculum level consistent with her or his current level of functioning. This opens the curriculum designed for older students to younger, highly able students. Frequently, curricular flexibility options may be utilized by the school system and the child without incurring additional costs and with minimal time commitment from classroom teachers. One of the most effective curricular flexibility options is subject matter acceleration, wherein students are placed into courses based upon ability level, regardless of age. For example, a mathematically able seventh-grade student is identified as possessing the prerequisite skills for the advanced mathematics curriculum. The school places her in the ninth-grade algebra course. Her academic needs are met without developing a new curriculum and with the added benefit of providing her with peers at her intellectual ability level. Subject matter acceleration has been used successfully at all ages and grade levels to provide challenging curriculum for academically able students.

Subject-matter acceleration is also accomplished through compacting the curriculum (i.e., completing two years of a course in one year). For courses using diagnostic pretesting, the curriculum may be compacted by completing only those components not already mastered. Fast-paced summer academic courses provide students an opportunity outside of their school to complete up to a full year of a high school course during an intensive 3-week program. Local colleges and universities are increasingly opening their doors to high school students to complete courses in specific subject areas. This option has the added benefit of students accruing college credits prior to attending college as a full-time student.

Other curricular flexibility options to consider include condensing grades 9 through 12 into a 3-year time span or allowing the student to leave high school without a diploma and enter college early. A number of undergraduate institutions have specific programs for students who leave high school after the 10th or 11th grade. Advanced Placement courses provide collegiate level course work without leaving high school. AP courses are offered in over 30 disciplines; schools without formalized AP programs can offer supervised independent study arrangements using AP syllabi. Mentoring and internship opportunities with individuals from the community allow students to conduct research or explore other opportunities not available in the school curriculum.

When developing interventions, the team should consider the importance of grouping students by ability. When grouping is combined with appropriate accelerative and enrichment opportunities, as well as changes to the curriculum to accommodate for ability, significant gains in academic achievement have been demonstrated (Kulik & Kulik, 1992). Gifted students also benefit socially by having a peer group to interact with. The advantage of the educational team approach to gifted education is that often the team is able to provide guidance for a number of students, opening up the possibility that like-ability students may be grouped together and have access to similar educational experiences.

An educational plan. An educational plan may include the following components:

1. Courses to be completed during each semester as well as summer educational experiences.

2. Enrichment opportunities available through the school.

3. Extracurricular activities which will supplement educational experiences.

4. Community-based experiences such as mentoring programs, local science center courses, and art center courses.

5. Academic year correspondence courses from colleges and universities.

6. Academic year courses completed at local colleges.

As an example, examine the outcome of Jeffrey's educational plan developed during his sixth grade. For the remainder of the year, Jeffrey completed his sixth-grade courses in social studies and language arts with his classmates. His teacher designed an independent study course in mathematics compacting the seventh- and eighth-grade curriculum based upon the diagnostic testing results. Jeffrey completed the sixth-grade science curriculum and also worked with a mentor from the local science center to complete an independent project in astronomy. His parents transported him to the science center on two Saturdays a month for this experience. During that following summer, Jeffrey attended a language camp, which introduced him to Russian language and culture. He also completed Junior Great Books sponsored by the local library. During his seventh-grade year, Jeffrey was placed into Algebra I with the ninth-grade students. In addition, he was placed into ninth-grade Earth Science and Spanish I. He completed seventh-grade English and Social Studies with his enrichment activities focused upon those courses. Additionally, he participated in band, chorus, chess club, basketball, and track. During the summer after his seventh-grade year, he attended a summer academic program mastering two semesters of computer programming in 3 weeks. Future educational plans include continuing with his mathematics sequence through his sophomore year of high school and completing calculus at the local university during his junior and senior years. He will take AP History and AP Literature and Composition while in high school so is doubling up on courses in these areas during his freshman and sophomore year of high school. Jeffrey has considered compacting his high school course work into 3 years but is currently undecided concerning that option.

As is obvious from Jeffrey's plan, carefully selecting appropriate accelerative and enrichment activities based upon the data provided during the identification and assessment stage is critical to a manageable plan. During this phase of the intervention, the school psychologist may act as a consultant, working with the team, parents, and student to make effective educational decisions. To understand the opportunities for gifted students available in each state, a primary source of information is the state gifted and talented association as well as local associations for parents of gifted students. These organizations often act as clearinghouses of information concerning opportunities for gifted children.

Plan Implementation

Once the educational plan is complete, the student and educational team meet to organize a strategy for implementation and placement. Educators, administrators, and coordinators of summer programs may need to be contacted concerning the availability of curricular options or courses. University-based programs usually have eligibility requirements for summer programs and completion of college course work. Thus, parents or the student should inform themselves early of the appropriate tests or entrance requirements so that the student may complete the requirements during the school year.

Contact with administrators throughout the development of the educational plan is essential as it will ensure that the placement decisions and appropriate curriculum are available through the school or community. In some cases, the school's traditional policy concerning course sequence, grades for access to a course, and acceptance of outside course work may need to be reconsidered. In these situations, the school psychologist may act as an advocate for gifted learners with administrators and school board members, ensuring that these individuals have a professional understanding of the needs and academic abilities of the gifted student, as well as the research supporting the effectiveness of these options. The school psychologist may often choose to work with the gifted and talented teacher in the role of liaison between the teacher and the school officials, explaining the rationale behind the educational plan developed for the gifted child. It is critical that sufficient assessment data from multiple domains be collected to adequately plan the interventions and justify implementation.

Evaluation of Student Progress

Although teachers consistently and appropriately monitor student progress within the classroom, little research is available providing guidance in the evaluation of appropriate academic placement of gifted children. One difficulty in evaluating progress is the focus on enrichment. Enrichment programming is usually focused on increasing problem-solving and creative-thinking skills and completing appropriate projects and research activities. Few formalized assessment instruments validly measure growth in the skill areas. A strategy of assessing growth, however, using both formative and summative procedures focused upon academic performance may provide a system of effective progress monitoring for the gifted student's educational plan.

Formative evaluations, in which the teacher and student monitor growth regularly throughout the school year, provides the first indication of the level of success of the academic placement. Gifted students are excellent candidates to use self-assessment strategies, where the gifted student is responsible for the identification of strengths and weaknesses in the process and outcome of projects as well as academic performance in accelerative educational placements. Diagnostic testing followed by prescriptive instruction falls naturally into a formative evaluation strategy for the teacher and gifted student. Performance on end-of-chapter and end-of-section examinations compared with performance on pretests quantifies growth within the specific subject matter as well as tracks progress throughout the academic year. Finally, formative evaluations which draw upon teacher ratings of student's academic performance, as well as interpersonal and social functioning within the classroom, provide additional data which may be used to evaluate appropriateness of academic placement in meeting student needs.

Summative evaluations, which track progress from year to year, provide additional evidence of student growth and continued academic challenge. The same out-of-level tests used for identification (e.g., SAT, ACT) may be completed upon a yearly basis, providing evidence of continued academic growth. Additionally, performance in specific areas targeted for growth is one indication of success of academic placement. As a rule of thumb, when students are completing the SAT at the junior-high-school age, their scores increase approximately 40 points from one year to the next on the SAT-Math and SAT-Verbal. Tracking growth with out-of-level tests is problematic for those students who have achieved a high score on initial testing. Again, the ceiling of the test becomes problematic. For these students, higher level performance on out-of-level tests is an inappropriate expectation given the limitations of the test in measuring increased performance at the extremes.

The evaluative process also is an identification process, providing the data from which future educational placement decisions develop. Summative evaluations, such as out-of-level tests, provide data concerning both the abilities and needs of the student. Formative evaluation data provide evidence of the motivation and behavioral responses of the student to the academic placement decisions made during the previous school year. With this data, the educational team may revise and refine the individualized educational plan and make recommendations for appropriate placement for the upcoming year.

Jeffrey's evaluative procedure was a combination of formative and summative strategies. Throughout his seventh-grade year, Jeffrey's progress through algebra, earth science, and Spanish I was tracked by his teachers, who regularly conferenced with the TAG coordinator concerning his progress. Jeffrey's algebra teacher noted consistently high performance on assignments and end-of-chapter tests; Jeffrey was even asked to study with a group of the ninth-grade students for some of the examinations. Earth science was an academic challenge for Jeffrey, yet he willingly invested additional time into his homework to perform at an appropriate academic level. Moreover, he was consistently at the top of his seventh-grade class in English and social studies and the teacher and self-evaluations of his enrichment activities indicated he was rapidly developing strong critical thinking skills and verbal and written communication skills. In the spring, he completed the SAT for a second time, scoring 650 SAT-Math and 360 SAT-Verbal. He has shown adequate growth in both areas. His verbal abilities, however, have shown significant improvement from his previous performance.

Special Populations

The limited scope of this chapter precludes an in-depth discussion of special populations of gifted students, students who are at risk for underachievement due to the occurrence of medical, intellectual, or environmental factors that complicate the development of that student's special abilities. Seeley (1993) provides an excellent chapter addressing the issue of gifted students who are at risk due to factors such as physical or medical disabilities (e.g., blindness, deafness, cerebral palsy), learning disabilities, emotional disorders, delinquency, low income or culturally diverse individuals (this category is confounded by race and ethnicity), and school environment. Additionally, information concerning learning disabled gifted students may be found in Silverman (1993). Educational planning for special populations within the gifted community, however, is approached with the same strategy and emphasis on appropriate educational placement. The consideration of alternative testing situations, individualized curricular materials or instruction, and focusing on the strengths of the special student allows the educational plan to meet the academic needs of each student.

The identification and inclusion of minority students within the gifted population has proven to be a politically sensitive task. Traditional methods of identification, such as academic achievement and performance on standardized tests, has resulted in an underrepresentation of minority students (Richert, Alvino, & McDonnell, 1982). Identification of gifted students through peer, teacher, and self-nomination may be an alternative solution. It must be noted, however, that these methods are not as psychometrically sound as standardized testing. Additionally, the Raven's Progressive Matrices is often promoted to be used in the identification of minority children. For further discussion of this topic, the reader may want to consult Baldwin (1991).

SUMMARY

School psychologists working with gifted students and their parents, teachers, and school administrators have the skills to ensure that this special population within the school is not underserved. As operationally defined in this chapter, a child who shows exceptional abilities within a specific talent area is identified as gifted in that area. Specifically, the discussion focused on the issues of serving students with identified academic talents and the ways school psychologists, through consultation, problem solving, and advocacy, can aid schools in making appropriate educational decisions regarding gifted learners.

Three interventions are commonly used to facilitate the education of gifted students: acceleration, ability grouping, and enrichment. Of these three, acceleration will effectively and economically provide a means of serving students of high ability with resources readily available in the school. Additionally, it served as the focus here due to its widespread research support. Acceleration, which in actuality is the concept of curricular flexibility, meets the needs of gifted students by placing them in a curriculum commensurate with their current level of ability. The school psychologist, through guiding the process to screen, identify, and assess the current level of development of the gifted learner plays a critical role in assisting an educational team to develop an appropriate educational plan resulting in a better student/curriculum match. Finally, through progress monitoring and program evaluation the intervention's effectiveness can be determined and modifications made where needed.

These interventions used within gifted education also address an important component of working with gifted children, providing a peer group at the same intellectual and social level with whom the gifted child can interact. This appropriate peer interaction, which is focused upon peers at a similar intellectual level rather than age, fosters an atmosphere in which social development can proceed optimally. Although not directly addressed, this outcome of acceleration, ability grouping, and enrichment may provide another important intervention with gifted children. Therefore, using the framework provided, the school psychologist may begin to address both the academic and social needs of the gifted child within his or her school.

ANNOTATED BIBLIOGRAPHY

Colangelo, N., & Davis, G. A. (Eds.). (1991). *Handbook of gifted education.* Boston: Allyn & Bacon

This edited volume contains contributions by eminent authors in gifted education. It is divided into six sections including the conceptions and identification of giftedness, instructional models and practices, creativity and thinking skills, psychological and counseling services, and special topics that apply to gifted education.

Gallagher, J. J., & Gallagher, S. A. (1994). *Teaching the gifted child* (4th ed.). Boston: Allyn & Bacon.

This volume provides guidance and practical suggestions for educators of the gifted. The most applicable chapters include specific curriculum and content modifications for the education of gifted students. Additionally, school psychologists working in a consultative role will find the chapter on administration particularly useful.

Heller, K. A., Monks, F. J., & Passow, A. H. (Eds.). (1993). *International handbook of research and development of giftedness and talent.* Oxford, England: Pergamon Press Ltd.

A world perspective on gifted education from respected researchers from different countries is provided within this edited volume. Specific sections include a focus upon nurturing gifts to their fulfillment, identification of giftedness, and the conception/development of giftedness.

Silverman, L. K. (Ed.). (1993). *Counseling the gifted and talented.* Denver: Love Publishing Company.

This edited volume delineates counseling and developmental strategies for a wide variety of populations of gifted students. Specific chapters focus on the emotional and social needs of learning disabled gifted, multicultural gifted students, at risk students, families of gifted children, and career guidance and group counseling with gifted students. The focus is on prevention rather than remediation.

Wang, M. C., Reynolds, M. C., & Walberg, H. J. (Eds.). (1991). *Handbook of special education.* New York: Pergamon Press.
Only one of the three sections within this handbook is focused upon gifted education; however, the carefully chosen authors and topics skillfully apply the current research in gifted education. Topics covered include acceleration, enrichment, social-emotional development, and special populations of gifted students.

Best Practices in Working with Single-Parent and Stepfamily Systems

Cindy Carlson
The University of Texas at Austin

OVERVIEW

It is no longer appropriate in the United States to consider the normative family environment for child rearing to be a household in which two biological parents reside with their children. Both single-parent and stepfamily systems have become increasingly common. Between 1960 and 1988 the proportion of families headed by single mothers more than doubled. It is projected that in the 1990s nearly half of all children alive today, and 85% of African-American children, will spend some portion of their life in a single-parent home; 40% of children are projected to live with a stepparent before age 18 (Glick, 1989). It is the purpose of this chapter to inform school psychologists about the most recent research findings associated with the adjustment of children in single-parent and stepparent homes and to provide recommendations regarding interventions at multiple system levels using a problem-solving framework.

ESSENTIAL BACKGROUND

Definitional Issues

In its narrowest definition *a single-parent family* refers to households in which an adult raises children alone without the presence of a second adult (Weiss, 1979). Single-parent homes may result from marital divorce or separation, death of a spouse, or a parent never marrying. When single parenting is the result of separation or divorce, these families are sometimes termed binuclear to reflect the reality of children visiting two linked households. Because over 90% of single-parent homes are headed by mothers, these homes are also frequently termed female-headed, mother-only, or fatherless families (Angel & Angel, 1993). Although most frequently mothers, a single parent may also be a father, a grandparent, or other relative or nonrelative. It is important to keep in mind that many families identified as single-parent by school or census records, for example, in fact have additional adults in residence who, to a greater or lesser extent, provide support to the household. Up to 34% of single parents have at least one additional adult relative in the home, with the highest percentages associated with young, never-married mothers (Hernandez, 1988). In addition, many single-parents have live-in partners. It should be expected that these diverse single-parent households are different psychologically, emotionally, and functionally for both adults and children (see Carlson, 1987, 1992 for further discussion).

A *stepfamily household* is one in which at least one adult is a stepparent to a child residing with them (Coleman & Ganong, 1991). This differs from the frequently used broader definition of *stepfamilies* referring to a family system created by marriage in which one or both of the spouses have children; however, the children may or may not reside full-time in the home (Ahrons & Wallisch, 1987, cited in Crosbie-Burnett & Skyles, 1989). Stepfamilies have multiple forms including the following: stepfather homes (mother with children marries a man with no children), stepmother homes (father with children marries a woman with no children), blended or complex families (both spouses have children), and binuclear home (single-parent whose spouse marries). In addition, numerous permutations of each of these stepfamily forms exist depending upon the custodial arrangements of the children. As with the heterogeneity of single-parent households, it is expected that each variation of stepfamily has distinctive features and emotional processes. (For further discussion see Carlson, 1985, 1990, 1991c).

In summary, both single-parent homes and stepfamilies are characterized by diversity, not homogeneity. The within-group variations in single-parent and stepfamily systems is seldom addressed in research. Thus, current knowledge of the complexities of these systems and their differential impact on the psychological well-being of children is quite limited. Information is most comprehensive for divorce, single, female-headed homes and for stepfather families. These family forms are most characteristic of the European-American population within the United States.

The Demographic Context

Race, ethnicity, and socioeconomic status dramatically influence the likelihood that a child will reside in a single-parent or stepparent home, the antecedents of such living arrangements, and the degree to which these living arrangements are associated with risk to children. The term *ethclass*, the combined influence of ethnicity, race, gender, and socioeconomic status, has been coined to underscore the importance of understanding how these variables combine to form a hierarchy of risk and resiliency for children in single-parent and stepparent homes (Kissman & Allen, 1993).

Single parenting is only rarely encountered among certain ethclasses, whereas in other groups it is encountered so frequently as to constitute the normative family form. By 1988, 12% of Asian-American children, 16% of European-American children, 27% of Hispanic children, 29% of American Indian children, and 51% of African-American children were living in female-headed, single-parent homes (Laosa, 1988). It is important to be cautious about possible racial biases related to these statistics as single parenting also varies as a function of residential ecology. There is a dramatic increase in single-parent homes across ethnic and racial groups, for example, as one moves from a rural to urban setting (Laosa, 1988). Thus, European-Americans located in the central cities show a higher incidence of single parenting than African-Americans living on farms.

Ethclass also dramatically influences the causes giving rise to single-parent homes. The most frequent precursor of single-parenting for European-Americans is divorce, for African-Americans out-of-wedlock births, and for Hispanics marital separation; only a small percentage of children reside in single-parent homes due to death of a parent — a finding consistent across racial and ethnic groups (Laosa, 1988). Laosa (1988) alerts us to the importance of considering within-group ethnic diversity in conjunction with family form. For example, there is an exceedingly high incidence of single parenting among Puerto Rican Hispanics comparable to the African-American population, whereas Cuban-Americans and Mexican-Americans have ratios of single-parenting closer to the European-American population.

Incidence of single fathering also varies with race and ethnicity. Although single fathers still represent only a small proportion of single-parent homes, the number had climbed from 616,000 households (approximately 2%) in 1980 to 1.1 million by 1989 (Downey & Powell, 1993). Single fathering is most common among Asian-American and European-American populations and least characteristic of African-American and Hispanic groups (Laosa, 1988). Another family composition characteristic associated with race is the relatively high proportion of African-American children (12%) who reside with neither parent in contrast with European-American (1.8%) and Hispanic (2.8%) children. This family pattern has been associated in the African-American culture with a broader, more informal and flexible kinship and social network structure that permits informal adoption of children by nonrelatives and/or relatives.

Remarriage rates resulting in the formation of stepfamilies also vary by ethclass (Hernandez, 1988). European-American parents are most likely to remarry; Hispanic parents are least likely to remarry; African-American parents form an intermediate group. Among both African-American and European-American groups, mothers who are less educated are most likely to remarry (Coleman & Ganong, 1991). As Catholicism is associated with lower remarriage rates, this is a likely factor among the Hispanic population. Among the urban poor, the lack of marriageable men is a factor in low remarriage rates (Angel & Angel, 1993). Regarding first marriages of adolescent mothers, European-Americans are almost twice as likely to marry within 5 years of the birth of the child as are African-American teenage mothers (Astone, 1993).

Not only do European-American individuals remarry at a high rate, they remarry relatively soon after a divorce. Th median interval between divorce and remarriage is only 3 years (Bumpass & Sweet, 1989, cited in Furstenberg & Cherlin, 1991). Moreover, it is common for a birth to occur in remarriage. Thus, 25% of preschool children gain a sibling in the first 18 months following remarriage (58% if the mother is under 25 years of age), and one-sixth of early adolescents gain a half-sibling (Bumpass, 1984, cited in Furstenberg & Cherlin, 1991). Each of these events — divorce, remarriage, sibling additions — represent significant family transitions for children.

Economic and Social Well-Being

Perhaps the most glaring difference between single-parent homes and two-parent systems, including stepfamilies, is disparity in economic well-being. *Single mothers and their children comprise the largest segment of the population in poverty in the United States.* Sixty-eight percent of African-American, more than 50% of Hispanic, and nearly 40% of non-Hispanic European-American female-headed households live in poverty (Angel & Angel, 1993). Although for a significant fraction serious poverty and welfare dependency is chronic (Angel & Angel, 1993), a sizable majority become poor at the time of marital disruption (McLanahan & Booth, 1991). Income following divorce has been found to drop approximately 70% for women, whereas the income for men remains about 90% of predivorce levels (Weitzmann, 1985). The feminization of poverty is maintained by the low earning capacity of women, lack of child support from the nonresidential father, and meager state welfare benefits (McLanahan & Booth, 1991). Single mothers face a double disadvantage — as women in the labor force their wages average 60% of males in comparable jobs, and as single parents they face alone the high costs of child-care while working (McLanahan & Booth, 1991). Not surprisingly, many deficits found for children reared in single-parent homes, when compared with children in intact homes, disappear when socioeconomic status is considered.

The economic situation is most serious for adolescent mothers, particularly minority adolescent mothers. The primary route out of poverty for single mothers is marriage o remarriage. Adolescent mothers have lower marriage rates than other women and thus are more likely to remain single and at economic disadvantage. Adolescent mothers are also more likely to divorce if they marry and thus to re-form economically at-risk mother-only families (Astone, 1993). Out-of-wedlock births, the interruption of schooling, the lack of marriageable (employable) males, fewer employment opportunities, and the emotional immaturity of adolescent mothers have serious social and economic consequences for both the mothers and their children. Children of young mothers have been found to be more likely to experience behavioral problems, do poorly in and drop out of school, nd face restricted employment opportunities (Angel & Angel, 1993). Adolescent girls who do poorly in school and reside in a single-parent home are more likely to become young single parents (Angel & Angel, 1993). Thus, there is fairly convincing evidence that early pregnancy and low educational attainment are the primary mechanisms through which poverty is transmitted from mother to children.

Social Bias

The demographic context of the single-parent and stepparent family might appropriately be considered a dimension of objective social reality. In contrast, constructed social reality reflects the degree to which objective facts about these family systems, which clearly are elusive given their diversity, are colored by social glasses. Two distinctive viewpoints have characterized discussion and research of the single-parent and stepparent family structures. The one is a *problem-oriented* or *deficit-comparison perspective*, whereas the other is a *normative adaptive perspective* (Coleman & Ganong, 1991). In the former there is the assumption that children in both single-parent and stepparent homes will be deficient in some manner when compared with children in nuclear families. Numerous hypotheses underlie the problem-oriented viewpoint. These include greater stress, differential socialization patterns, additional or deficient numbers of adults in family roles, differences in attachment related to biological discrimination, and incomplete institutional support for these family variations when contrasted with nuclear intact families. Despite the prevalence of single-parent and stepfamily homes, the problem-oriented perspective is deeply rooted in current American society.

The *deficit-comparison perspective* is also widespread within the public schools. Fuller (1986) found that teachers associated positive, conforming behaviors with children from intact homes and more often associated negative, disruptive behaviors with children from single-parent families. Teachers older than 36 years of age were most extreme in their biases. One exception to this bias was the greater likelihood of children in single-parent homes being perceived by teachers as independent. A similar negative bias in attitudes of school counselors and social workers was also found regarding children from stepfamilies, when compared with children in intact homes (Bryan, Ganong, Coleman, & Bryan, 1985, cited in Crosbie-Burnett & Skyles, 1989).

In contrast to the problem-oriented or deficit-comparison perspective, a *normative-adaptive perspective* considers single-parent and stepparent systems to be normative lifestyle choices that are firmly established in society. Rather than examining deficits in children's adjustment, understanding the ways in which competent children are reared in *diverse* family forms is the goal of this perspective. Far less research is available to guide interventions with children and families based on the normative-adaptive perspective. Every effort will be made within this chapter to examine single-parent and stepparent families as normative lifestyle choices, despite the fact that this is not the prevalent social viewpoint.

PROBLEM IDENTIFICATION: CHILD OUTCOMES ASSOCIATED WITH SINGLE-PARENT AND STEPPARENT HOUSEHOLDS

It is critical for practitioners to bear in mind that a sizable percentage of children in single-parent families and stepparent families thrive, and many children in intact families do not. As has been noted by multiple authors and studies, family structure does not, in and of itself, explain child and adolescent well-being. What matters most is what happens within the family. *On the average*, however, current research suggests that children fare better in intact, two-parent homes than in either single-parent or stepparent households, regardless of socioeconomic status. Differences, however, may be slight. Recent research suggests that outcomes associated with rearing in a single-parent or stepparent home are most strongly influenced by family processes and gender of the child.

SINGLE-PARENT HOMES

Educational Problems

Early research found rearing in a single-parent home to be associated with lower cognitive functioning, lower school achievement, lower achievement motivation, and a "feminine" cognitive style. Negative effects were consistently found to be more pronounced for boys than girls and most applicable to postdivorce, single-mother-headed homes (for review see Carlson, 1987; Emery, 1988). Several recent large-scale studies, which control the effects of socioeconomic status (SES), suggest that children in single-parent homes are at a slight, but practically speaking insignificant, disadvantage for educational attainment compared with children in intact homes. Of greater concern is their dramatically increased risk for school drop-out.

A large ($N = 58,000$), national, random probability sample of 10th and 12th graders found slight, but practically small, differences in achievement test scores and high school grades between children in single-parent homes and intact homes (Zimilies & Lee, 1991). Girls get better grades than boys in both intact and single-parent homes. Similar findings of statistically significant, but practically small, differences in school achievement were obtained in a meta-analysis of 92 studies of postdivorce children (Amato & Keith, 1991). In a noteworthy study of single-father homes, a large scale survey of eighth graders found educational benefits to girls living with fathers including higher educational expectations, better science and history test scores, and greater access to educational resources including home computers and newspapers.

Although differences in educational achievement are slight between children in single-parent and intact homes, disturbing data have emerged regarding the greater risk of children in single-parent homes to drop out of high school. Zimilies and Lee (1991) found students from single-parent homes to be *almost three times as likely to leave high school before graduation* as were those from intact families, despite the fact that their grades and achievement test scores were relatively comparable to students in intact families. This pattern persists after statistical adjustment for SES differences between the groups. Significant triple interactions between drop-out behavior, gender of the child, and family structure suggest complex relationships. Specifically, males, when residing in mother-headed single-parent homes, were found to be at greater risk of school drop-out than when residing in father-headed single-parent homes. In contrast, when females reside with a single-parent mother, drop-out rates are low whereas residing with a single father increases the risk of dropping out. Zimilies and Lee (1991) note that the higher drop-out risk of boys in single-mother homes and girls in single-father homes existed despite school achievement comparable to peers. In fact, girls in single-father homes who later dropped out of school actually had higher achievement test scores than their counterparts who stayed in school, leading these researchers to conclude that high school drop-out appears to be more a function of social deviance than cognitive deficiency (Zimilies & Lee, 1991).

Problems of Adjustment and Social Deviance

Earlier research on the social and personality effects of rearing in a single-parent home (for reviews see Carlson, 1987, 1990, 1992; Emery, 1988; Hetherington, Stanley-Hagan, & Anderson, 1989) found this family constellation to be associated in boys with greater difficulty with self-control, higher rates of antisocial and delinquent behavior, lower moral development and maturity, and a less secure masculine style. For girls, negative effects were seldom obtained; however, a few early studies found that maturing girls in single-parent homes may be at risk for early onset of sexual behavior in contrast with peers in intact homes.

Recent research, based on a large-scale survey, finds that adolescents in single-parent families are, *on the average*, clearly at more risk than those in two-parent, intact families (Benson & Roehlkepartian, 1993). Areas of greater risk for single-parent youth include alcohol use, tobacco use, depression, suicide, antisocial behavior, and sexual activity. On average, youth (both middle school and high school) in single-parent families were involved in 3.96 of 20 risk behaviors compared to 2.65 risk behaviors among youth in intact homes. These results remained when race, maternal education, and age and sex of the child were controlled. According to the researchers, the impact of rearing in a single-parent family, however, appeared to be more negative for European-American youth than for youth of color.

A meta-analysis of 92 studies (data from over 15,000 children) comparing children living in divorced single-parent families with children living in continuously intact families on measures of well-being, found children of divorce to score lower across a variety of outcomes (Amato & Keith, 1991). Although statistically significant, the differences in well-being between these groups were generally weak (.14 of one standard deviation on average).

A study of depressive affect in early adolescents in intact versus single-parent families found that youth in single-parent families were more likely to be depressed than their peers in intact homes (Feldman, Rubenstein, & Rubin, 1988). Further analyses revealed, however, that family structure was only related to adolescent depression when the adolescent also perceived his or her family to be lower in cohesion and parent–child communication to be unsatisfactory. Youth in single-parent homes were at particularly high risk for depression if these family conditions co-existed with low perceived friendship support. Friendship support clearly offset the negative impact of processes within the single-parent family. Family structure was not related to friendship support. Therefore, youth who lack both the support of friends and perceived family support may be at high risk for continued depression. In summary, the studies mentioned here clearly indicate statistically significant differences in the educational achievement and psychological adjustment of children in single-parent homes when compared with children in two-parent, never-divorced homes. These differences, however, are frequently quite small practically speaking except for high school dropout rates. The fact that differences exist at all, however, between these two family forms suggests factors which may operate to differentiate single-parent and two-parent, intact homes.

Family Processes Associated with Children's Problems

Research consistently finds that the quality of parenting is a stronger predictor of child competence in single-parent homes than any other variable. Single parents are vulnerable to permissive parenting styles characterized by few or inconsistent rules, low monitoring, and low involvement in school (Dornbusch et al., 1987). Whereas earlier studies found permissive parenting to be more characteristic of single mothers and viewed this as a key factor in the differential adjustment of boys versus girls in mother-headed families, recent research has found permissive parenting to be characteristic of both mother-headed and father-headed single-parent homes (Dornbusch et al., 1987).

Single parents are also more vulnerable to violence and abusive forms of parental control. Gelles (1989), in a national survey of 6,000 households, found that single parents were significantly more likely to use abusive forms of violence towards their children than parents in dual-caretaker homes and concluded that "the single parent household is at particularly high risk for physical abuse of children" (p. 498). Poverty and its associated stressors placed children at greatest risk of violence in single-mother-headed homes with these mothers reporting a 71% greater rate of very severe violence toward their children than did mothers in two-parent homes. Presence of another caretaker in the home (16% of single mothers lived in a household with one or more other adults) did not alter rates of violence toward children; in fact, rates of severe and very severe violence were actually higher in these homes. The rate of severe and very severe violence toward children, however, was highest in single-father families, particularly homes with incomes below $10,000. *The rate of very severe violence in low income single-father homes (406 per 1000) is higher than any rate of severe violence observed in any other subpopulation of parents* (Gelles, 1989).

In summary, children in single-parent homes, both mother-headed and father-headed, may experience adjustment problems associated with permissive parenting. When combined with poverty, these children may be at particularly high risk for severe and abusive violence. These risks were corroborated in a large-scale survey of adolescents (Benson & Roehlkepartain, 1993). The average youth in single-parent homes was more likely to have experienced home environmental deficits including physical abuse, sexual abuse, parental addiction, time alone, stress, and television overexposure when compared with youth in intact homes.

Interparental conflict is another family process that increases risk for children in single-parent homes. Amato and Keith (1991) concluded based on their meta-analysis of 92 studies, that family conflict was the most significant predictor of children's adjustment in postdivorce single-parent homes. Johnston (1990) found that hostile and noncooperative relationships between divorced spouses were related both to diminished parenting capacity and poorer child outcomes. Specifically, children's interpersonal competence and an absence of behavior problems were predicted where parents maintained a successful coparental alliance after divorce and where family role structure remained clear and parental warmth remained intact. In a similar study with adolescents, Fauber, Forehand, Thomas, and Wierson (1990) found interparental conflict to predict single-parent rejection/withdrawal, which, in turn, predicted adolescent adjustment problems. This was in contrast with the causal pathways for intact families where interparental conflict directly influenced adolescents negatively but did not affect parenting style.

In summary, these studies consistently point to the undermining role that interparental conflict has on the competence of the custodial single parent, which, in turn, relates to negative outcomes for children. Results suggest that noncustodial parents can most effectively promote the social competence of their children by supporting the parenting of the single custodial parent. Other factors contributing to ineffective parenting in single-parent homes are role strain and maternal depression. A study of never-married (66.7%) single mothers ($N = 225$) in poverty (more than 90% of sample had annual income levels below $10,000 despite the majority having completed high school) revealed a high rate of depressive symptoms (59.6% compared with the general population rate of 8.7%; Hall, Gurley, Sachs, & Kryscio, 1991). Maternal depressive symptoms and quality of the mother's primary intimate relationship predicted poor parenting attitudes, which, in turn, predicted child behavior problems. The more severe the mother's depressive symptoms, and the poorer the quality of her primary intimate relationship, the less favorable were maternal parenting attitudes. More severe depressive symptomatology was associated with greater numbers of everyday stressors, fewer social resources (i.e., functional social support and quality of family relationships), and greater use of avoidance coping strategies.

Family Processes Associated with Resiliency

While on average youth in single-parent families are more likely to be at risk than those in intact homes, this is clearly not inevitable. Benson and Roehlkeparten (1993) found $^{1}/_{2}$ of middle-school and $^{1}/_{4}$ of high-school-aged youth in single-parent homes to be at low risk. When the family assets are compared for single-parent homes with youth who thrive versus those who are at highrisk, thrivers were almost twice as likely to report living in homes characterized by family support (including turning to a parent for social support and having a parent involved in their schooling), parental control (including having explicit parental standards for behavior, discipline for broken rules, parental monitoring of whereabouts, and fewer than three nights out per week for fun). These same resilient youth expressed higher levels of internal assets including motivation to achieve, valuing of sexual restraint, and self-esteem. Resilient youth in single-parent homes were also more likely to report extrafamilial assets of positive peer influence, positive school climate, and involvement in structured activities (e.g., church, school extracurricular, lessons). These results lead the researchers to conclude that, "Many of the differences in assets between single-parent youth who thrive and those who do not point toward the support systems around families. It may be this external network of support is key to success in single-parenting" (Benson & Roehlkeparten, 1993, p. 9).

STEPPARENT FAMILIES

As with children in single-parent homes, although differences are seldom large, recent studies find stepchildren, when SES is controlled, to perform less capably on both educational and adjustment indices when compared with children in intact homes. When compared with children in single-parent homes, stepchildren seldom differ on these indices. Increasingly these differences are reliably associated with gender of the child and gender of stepparent such that the following conclusion appears warranted: The stepparent situation is comparatively beneficial for boys and comparatively detrimental for girls. The risk associated with remarriage appears to be heightened during early adolescence.

Educational Progress

Several large-scale studies have found children and adolescents in stepfamilies to demonstrate lower educational achievement than their cohorts in intact, nuclear families. When compared with children in intact homes, children and adolescents in stepfamilies have been found to earn lower grades (Dornbusch et al., 1987; Zimilies & Lee, 1991), have lower achievement test scores (Zimilies & Lee, 1991), rank lower in their class (Zill, 1988), and be twice as likely to repeat a grade (Zill, 1988). Stepparents have also been found to be less active than biological parents in school affairs (Dornbusch et al., 1987). Gender of the child, however, influences these results. Both the achievement test scores and school grades of males have been found to be considerably enhanced by living in a stepfamily (Zimilies & Lee, 1991).

Regarding school drop-out, as with single-parent homes, adolescents in stepparent homes have been found to be significantly more likely to drop out of school before high school graduation, despite the fact that their grades and achievement test scores are relatively comparable to students in intact families (Zimilies & Lee, 1991). For adolescents in stepparent families, however, the pattern is reversed from that obtained within single-parent homes, with drop out more likely in homes with a like-gender custodial parent. Thus, females in a stepfather home and males in a stepmother home have been found to be at greatest drop-out risk. According to one study:

> Thus, these results may be summarized by stating that when a mother decides to remarry, the probability that her daughter will drop out of high school rises sharply, whereas the likelihood that her son will drop out is almost halved. Similarly, but to a lesser extent, drop-out behavior among boys increases when their fathers remarry, while the tendency for daughters to drop out declines upon their father's remarriage (Zimilies & Lee, 1991, p. 318).

These complex results were interpreted by the researchers as being consistent with attachment theory which proposes that a strong attachment develops between the adolescent and same-sex parent that is perceived to be lost or threatened when the like-sex parent remarries. This is particularly true for adolescent females. On the other hand, when remarriage brings a same-sex parent into the family unit (as with the remarriage of a single mother with sons), the probability of drop-out decreases. This suggests that relationships within parent–child dyads of dissimilar sex are particularly complex.

Adjustment and Deviance

Overall it can be concluded that children in stepfamilies show greater psychological adjustment problems when compared with children in intact homes. Comparisons between children in stepparent and single-parent homes yield conflictual results with some studies finding adjustment to be similar and others reporting stepchildren are at greater risk.

Teachers report more behavior problems and school counselors report more contact with stepchildren when compared with children in intact homes (Crosbie-Burnett, 1988, cited in Crosbie-Burnett & Skyles, 1989). Stepchildren are consistently reported by parents and teachers to have more internalizing behavior problems (e.g., anxiety and depression) and more externalizing problems (e.g., fighting, poor peer relations) than children in nuclear families (Bray, 1988; Zill, 1988). Results across 92 studies (Amato & Keith, 1991) found children in stepfamilies, compared with children in intact homes, to be significantly lower in behavioral conduct, psychological adjustment, self-esteem, social relations, and marginally lower in academic achievement. Compared with children in divorced single-parent families, children in stepfamilies were significantly lower in psychological adjustment and marginally lower in behavioral conduct. These results indicate that children living with a stepparent exhibit considerably more problems than children in intact homes and suggests that parental remarriage does not "solve" problems of an absent or single parent. However, these findings vary with the sex of the child. *Across all studies and all outcomes, boys in stepfather families scored above boys in single-parent, mother-headed homes, whereas girls in stepfather families scored below girls in single-parent, mother-headed homes.*

Family Processes Associated with Child Problems

Evidence is mounting that early adolescence appears to be a developmental period of particular risk and vulnerability for children's adjustment to remarriage (Hetherington, 1989). In a longitudinal study of children's adaptation during early adolescence to remarriage, with comparison groups of single-parent homes and intact homes, Hetherington and Clingempeel (1992) found that the course of adaptation to remarriage in stepfather families is a very difficult one that shows little improvement over a 2-year period. Disruptions in family functioning accompanying remarriage of a single mother were pervasive and affected sibling as well as parent–child relationships. Children's behavior problems in these stepfamilies persisted despite good marital adjustment (Bray, 1992; Hetherington & Clingempeel, 1992) and irregardless of authoritative parenting by both parents (Hetherington & Clingempeel, 1992). This indicates that coping with marital transitions is particularly difficult for young adolescents and that factors beyond the quality of parenting play an important role in the adjustment of adolescents to stepfamilies. Zill (1988), in a large-scale national survey, similarly concluded that stepchildren whose families were disrupted in early adolescence showed elevated behavior problem scores in comparison to those whose families were disrupted in middle childhood.

Other factors associated with risk for stepchildren include parents' education, income level, and having half-siblings in the household (Zill, 1988). Stepchildren are at greater risk when parent education is low, income is low, and when half-siblings (versus no siblings or biological siblings) are present in the home. In a surprising result regarding parents' education, Zill (1988) found that within father-stepmother families high parental education level (college degree) predicted greater stepchild problems. It was surmised that more highly educated stepmothers may be more apt to try to play an active role in the family, and, in effect, take over as the child's mother. Given the child's continuing bonds with the biological mother, active parenting on the part of the stepmother may create conflict and resentment in the child. Regular contact with the noncustodial biological parent was found to be important for stepchildren in father-stepmother families but not in mother-stepfather families (Zill, 1988). Thus, contact with the noncustodial mother was more critical than contact with the noncustodial father. Children in stepfamilies experience a disproportionately high rate of abuse and neglect when compared with children in intact families (Crosbie-Burnett & Skyles, 1989). Both the lack of bonding and reduced incest taboos between stepparents and children have been given as explanations.

Family Processes Associated with Resilience

Stepfamily conflict and child symptoms are reduced when discipline and supervision of children remains in the responsibility of the biological parent, whether mother or father, particularly in the early stages of remarriage. Younger children adjust more favorably to a stepfather when he first works to establish a warm (not parental) relationship with his stepchildren, support the mother's discipline, with gradual movement into an authoritative parenting role (Hetherington, 1989, cited in Hetherington & Clingempeel, 1992). When stepfathers engage in control and supervision of children, not only is the stepfather-stepchild relationship attenuated, but the biological mother–child relationship is of poorer quality (Fine, Voydanoff, & Donnelly, 1993). For adolescents, warm, supportive, noncoercive parents who monitored their early adolescents' behavior but granted them considerable autonomy had the most well-adjusted stepchildren (Hetherington & Clingempeel, 1992). In short, stepchildren resent supervision from an adult with whom they do not have a close affectional relationship. The development of a close affectional relationship between stepparent and stepchild appears easier for younger children, who typically adjust to remarriage within 2 to 2.5 years (Hetherington, 1989 and Bray, 1990, cited in Hetherington & Clingempeel, 1992). This is in contrast to stepfamilies with adolescents where it may take 6 to 9 years for family cohesion to approximate levels typical of intact homes (Visher & Visher, 1988).

PROBLEM ANALYSIS

See Carlson, 1990, 1991c, for a comprehensive assessment process for single-parent and stepfamilies, which evaluates family processes on the dimensions of systems organization, family life cycle stage, parent–child relationship quality, social support, and coping style. In addition, an interview procedure for single-parent and stepparent families is available in Carlson (1985) and Visher and Visher (1988). Guidelines for conducting family assessments, including appropriate measures and methods, appear in Carlson (1991a, 1991b). A comprehensive assessment of the family system should be considered a critical part of the child assessment procedure.

It has been recommended that, in addition to completing a family assessment as part of a child referral, school psychologists annually screen their student populations for high risk family situations. Factors associated with risk in single-parent and stepparent families, which have been previously discussed, are summarized in Table 1. In addition to the risk factors noted, screening the student population for any family changes that have occurred in the past year (i.e., separation, divorce, death of a parent or loved one) or are anticipated in the current year (i.e., remarriage) would be useful to the formation of voluntary, prevention-oriented support or education groups for children and/or parents.

PROBLEM SOLVING

The clear goal of screening and assessment is differential diagnosis and the matching of treatment. School psychologists have many intervention options ranging from prevention to intervention, indirect versus direct intervention, and targeting the child, parent, family, teacher, or school. For purposes of clarity, the following recommendations for problem solving with single-parent and stepparent families are organized by the focus of intervention: child, parent/family, or school.

Child Centered

Small, time-limited, structured, school-based support-group interventions with children have been found to be effective for children experiencing family change. Studies have documented the effectiveness of such programs in modifying beliefs and attitudes about family change and teaching coping behaviors (Anderson, Kinney, & Gerler, 1984), reducing depression (Crosbie-Burnett & Newcomer, in press, cited in Crosbie-Burnett & Skyles, 1989), reducing anxiety (Pedro-Carroll & Cowen, 1985), and improving self-concept (Stolberg & Garrison, 1985). These groups have been designed primarily as interventions for children experiencing divorce; however, it can be expected that such groups would also be effective for other forms of family transition as well. Recent data on the difficulty associated with the transition to remarriage, particularly for children in middle childhood and early adolescence, would suggest that support groups for these children should be a high priority.

Individual counseling may be necessary for youth in crisis or in high levels of distress related to family conflict or transitions. Conflict between parents is common during family transitions which are marked by stress, anxiety, and loss. Clinicians have long noted that parents sometimes diffuse the stress of spousal conflict by "spilling" some of it onto children. Direct help should be provided to children specifically for coping with parental conflict, diminished parenting, and triangulation (Johnston, 1990). For all of these situations, it is important to help children (a) understand the reasons for parental behavior, (b) identify ways in which they exacerbate or ease the tension with their behavior, and (c) establish clear boundaries regarding their blame and responsibility for parents' actions. Self-help books may also be helpful to children and adolescents. Reviews of existing materials have been completed by Schlesinger (1986) on single-parent homes and Coleman and Ganong (1989) for stepparent homes.

In addition to child interventions targeted to the family situation, interventions facilitating general adjustment can also be expected to benefit children experiencing family stress. As noted previously, children fare better in family transitions when they are socially competent and academically capable and have friends (who do not get in trouble). Social skills interventions, tutoring, facilitating participation in extracurricular activities, and newcomer groups for children who have moved into the school district would all appear to be beneficial to youth in single-parent and stepparent homes.

Parent and Family Centered

The goal of parent and family problem solving is to enhance parenting skills despite the unique challenges of single-parent and stepparent homes. As noted in the previous discussion, issues associated with single parenting and stepparenting may diminish parental capacity and adversely affect children. In addition, research consistently demonstrates that authoritative parenting facilitates children's development in single-parent and stepparent homes. Parent interventions, therefore, should focus on developing the capacity of parents to engage in authoritative parenting. Methods of parent and family intervention include support and educational groups, parent skills training, parent/family consultation, and family counseling.

Group interventions have the advantage of cost-effectiveness and provide the opportunity to create social support for parents. Individual parent or family interventions are more costly but have the advantage

TABLE 1
Risk Factors in Single-Parent and Stepparent Homes

Lower Risk	Higher Risk
Both Family Types	
higher parental education	low parental education
economic well-being	low income
authoritative parenting	permissive/neglectful parenting
co-parental cooperation	co-parental conflict
later childbearing	adolescent parenthood
fewer children	more children
younger children	early adolescence
compliance during early adolescence	acting out in early adolescence
parental involvement in school	lack of school involvement
Single-Parent Homes	
mothers with daughters	mothers with sons
fathers with sons	fathers with daughters•
healthy custodial parent	custodial parent depressed
adequate social support	lack of social support
Stepparent Homes	
children younger at remarriage	remarriage with early adolescents
mother-son-stepfather families	mother-daughter-stepfather families
biological mother ties continue	stepmother replaces mother
no stepsiblings	stepsiblings

•Results of studies are suggestive but remain equivocal.

of more directly targeting a solution to the problem. Disadvantages of school-based parent and family interventions include getting parents to participate, role constraints on school psychologists, and adequacy of school psychologists' training in family dynamics and intervention (see Carlson & Sincavage, 1987). In the following discussion an overview of these intervention modalities will be provided followed by specific variations relevant to subpopulations.

Parent groups. Parent group interventions may take the form of support groups, education groups, and skills-training groups. Systematic skills training has been found effective in reducing child problems associated with both single-parent and stepparent homes. In a study evaluating the effectiveness of two treatment conditions (intensive parent training and parent training plus training in social problem-solving targeted for problems other than child management) with single mothers, it was found that both conditions produced improvement in children's externalizing disorders; however, the later condition produced greater decreases (Pfiffner et al., 1990). Systematic skills training with stepfamily parents found trained parents increased frequency of desirable parenting responses to their children and became more verbally responsive (Nelson & Levant, 1991). Stepchildren noticed positive changes in parents as well as on pre-/posttest measures.

Although the effects have not been systematically examined, support groups for single parents and stepfamily parents may also be of value. Kissman and Allen (1993) define social support as "help that is available in difficult or stress-arousing situations and feeling valued and belonging to a group" (p. 58). Social support network building requires relationship skills, emotional energy, available time, motivation, and a pool of contacts. These are in short supply for many parents, particularly single parents. The availability of these resources in one location, that is, a support group, would be highly desirable. In addition to providing an opportunity for developing social support networks, support groups can help parents learn ways to cope with stress created by negative societal views of single-parent and stepfamily homes (Fuller, 1986) and the lack of clear role expectations for stepparents (Crosbie-Burnett & Skyles, 1989).

Parent consultation/family counseling. School psychologists may find brief parent consultation is useful to single parents and stepparents for normalizing the stressors of these family situations, providing information about how family relationships may influence their child's behavior, providing guidance regarding appropriate behavior with noncustodial parents, providing assistance with the establishment of authoritative parenting practices, and facilitating communication between parents and teachers regarding family concerns and the child's achievement. Key to successful parent consultation by the school psychologist is learning about single-parent and stepfamily issues and concerted attention to one's own biases so that challenges faced by these parents are not viewed and communicated as being reflective of lack of competence.

Family counseling or referral for family counseling is particularly appropriate when conflict is present and chronic between family members in the single-parent/stepfamily system. Counseling with these families most frequently involves resolution of conflicts between family members and the clarification of appropriate roles and responsibilities. Lack of agreement on roles and responsibilities can fuel conflict. Some family dyads are particularly susceptible to conflict in single-parent and remarried systems. These include custodial-noncustodial parents; single mothers–sons; single mothers–grandparents; stepparents–stepchildren (particularly of opposite sex); and biological parent–child during early adolescence. Availability of school personnel for counseling during evening hours for parents who work during the day is, of course, desirable.

Stepfamilies and single-parent families also bring unique issues to counseling. Key developmental issues during the first years of remarriage include arranging for discipline and parental authority for children; forming a strong marital bond; and developing a workable relationship with the noncustodial parent (Bray, 1992). Single-parent homes, as noted, are particularly vulnerable to permissive parenting, role strain, and depressive symptomatology. All these are exacerbated if there is a conflictual or unsupportive relationship between the custodial and noncustodial parent. Specific counseling strategies for this have been specified by Morrissette (1987) and Glenwick and Mowrey (1986).

Special considerations of single-parent mother-headed homes. The primary concern of intervention with single mothers should be the provision of support. These parents are overburdened financially and experience considerable role strain as the wage-earner, child caretaker, and household manager. As such, they are commonly isolated from emotional and recreational support from peers and vulnerable to depression, irritability, and diminished parenting. Sources of support should be explored within the family, the school, and the community and among peers of the parent. Acceptance of the need for support can be difficult for single-parent mothers as the prevailing social belief is that families should be able to care for themselves and not rely on outsiders. This appears particularly problematic for European-American single mothers; the African-American, Native-American, and Latino cultures are more accepting of supportive kinship networks. Persons of color are also more accustomed and accepting of informal and flexible systems of exchange. These diversity considerations are important to consider in assisting single mothers with social support.

Adolescent single parents. Adolescent single parents, as previously noted, constitute the subgroup of greatest risk for poor parenting, poverty, chronic family disorganization, and child abuse and neglect. Effective intervention with adolescent single parents requires a comprehensive service delivery package that includes opportunities to continue schooling, childcare provision, economic support, child development knowledge, parenting skills training, and life skills training (Kissman & Allen, 1993). In addition, adolescent mothers may benefit from individual therapy or professionally led groups in which the conflicting demands of adolescence and motherhood are confronted and problem-solving strategies encouraged.

It should also be noted that between 65% and 85% of pregnant and parenting teenagers live with their families. Moreover, reviews of the research indicate that families play a large role in decisions both leading to and consequences resulting from teen pregnancy. The consequences of teen pregnancy — school dropout, poverty, repeat pregnancies, and prolonged dependence — are considerably more negative for teen mothers living alone than for those living with their families who provide them with the majority of material and psychological support. These facts suggest that programs for teen parents would be optimized by viewing the family, including the infant's father, as the client to receive program services. Currently, only the teen mother is generally targeted for intervention. Data from three federal programs find that family involvement in interventions, regardless of how measured and defined, is related to positive outcomes for the infant and teen mother (Hanson, 1992). These data also suggest that teen mothers who live alone with their children are at extremely high risk and should be a priority for intensive wraparound intervention.

Single fathers. Single fathers report the following difficulties: insufficient knowledge of child development and gender differences in development, developing the ability to nurture as well as to discipline children, balancing work and childrearing, lack of organized social support, reluctance to seek therapy, and minimization of feelings. In addition, single fathers commonly report more discomfort raising daughters than sons and more ease raising younger children versus adolescents. Many of these difficulties reflect socialized gender-related role difficulties in our culture. Single fathers tend to be less confident of their ability to nurture in contrast with mothers who end to lack confidence in their ability to discipline effectively. Because a primary source of self-esteem for males in our culture is work, balancing work and childrearing may impose greater strain on single fathers. Of particular note is the failure of many men to recognize feelings of loss and depression (Kissman & Allen, 1993). Single fathers may act out these feelings in ways destructive to their children, for example, imposing rigid rules and restricting visitation with the noncustodial parent. It is critical for school psychologists to keep in mind that impoverished single fathers, as noted in earlier discussion, had the highest rates of severe and very severe child abuse of all population subgroups (Gelles, 1989). Grief (1990) emphasizes that the best interventions for single fathers are those that link them with other single parents in a group format.

School Centered

Schools provide an important source of information, acceptance, stability, and support to children and parents in single-parent and stepparent homes. Recommendations for schools in facilitating the coping of these families have been made previously (i.e., Crosbie-Burnett & Skyles, 1989; Fuller, 1986; Johnston, 1990; Kissman & Allen, 1993; Montemayor, 1983) and will be incorporated into this discussion. School interventions may focus on policy changes, practice changes, or attitude changes.

Policy recommendations.

1. Ensure consistency of school policies toward single parent and stepfamilies. At present, legally married stepparents are conceptualized as replacements of biological parents for purposes of financial policies (e.g., college financial aid, free school lunch) yet are denied legal rights and responsibilities of biological parents in other policies (e.g., school permission slips, medical emergency release forms, access to school records, signing report cards). These policies undermine the authority of the stepparent, which may be fostered in the home, and attenuate an already fragile stepparent–stepchild relationship (Stenger, 1986, cited in Crosbie-Burnett & Skyles, 1989). Similarly, single custodial parents are granted all legal rights and responsibilities regarding their child, which undermine the involvement and authority of the noncustodial parent.

2. Assume and promote cooperation among adults involved with the child. School policies (which frequently require that only one parent attend special education review meetings, teacher conferences, or open house) send the message to parents that it is unnecessary to involve or inform more the distal or conflictual co-parent. The school represents a powerful social institution which can model and require that parents cooperate in the best interest of the child. All parental figures involved with the child should be regularly provided information about the child and invited to all meetings and functions regarding the child. The expectation of schools should be that only in circumstances where two or more parents are unable to sit in the same room with each other without engaging in violence or abuse should separate meetings be conducted.

3. Mail report cards and important announcements to nonresidential parents with information stating they have the right to access their child's record, to talk with the child's teacher, and so forth.

4. Annually collect and update information on the family structures of each student.

5. Maintain library resources that focus on the experiences of children in single-parent and stepparent families.

6. Review existing curricula for nuclear, intact family bias.

7. Provide/require/make available training on family structures to all school personnel and provide incentives for attendance. Crosbie-Burnett and Pulvino (cited in Crosbie & Skyles, 1992) report changes in attitudes and beliefs and feelings of competence among teachers and counselors in dealing with stepchildren following a 4-hour training session.

8. Ask single-parent mothers if they would like their children placed with male teachers and single-parent fathers if they would like their children placed with female teachers.

9. Allow for the many variations of family forms in any data collected by the school, district, or state.

10. Provide after-school activities so children can avoid going home to an empty house or to a conflictual home environment. Virtually everyone agrees this is important for elementary school-age children, but it is viewed as less essential for middle-school-aged youth. As a result, early adolescents in single-parent and stepparent homes are more peer-oriented than those in nonconflictual intact homes. Adolescents who are peer oriented rely heavily on peers rather than parents for emotional gratification, advice, and companionship and engage in more antisocial activities, many of which are committed during the after-school, unsupervised hours.

11. Consider the needs of working single parents in scheduling school activities and events.

School psychology practice.

1. Be informed about single-parent and stepfamily issues; conduct presentations and develop/distribute handouts with useful information.

2. Be available to communicate with all parents or individuals of psychological importance to the child.

3. Include all parents and persons of psychological importance to the child in any assessment of the child's problem.

4. Screen the student population for high-risk family situations.

5. Offer support and education groups to single parents, stepparents, and their children and adolescents.

6. Provide parent consultation and family counseling at least one evening per week or identify local mental health professionals who specialize in these issues and have evening hours.

7. Conduct your professional practice to facilitate communication between parents and with the expectation that parents are able to cooperate in the best interests of the child.

Facilitating nonbiased attitudes. Although it is seldom the intention of schools to discriminate in their policies or for school personnel to express biased attitudes, research consistently finds that society views both the single parent and remarried family system as deficient in comparison with intact, nuclear families. As professionals, school psychologists bear the responsibility for examining their individual biases as well as the unintended biases inherent in school practices and policies because these may contribute to child deficits. The following are recommended ways to facilitate nonbiased attitudes:

1. Expand the narrow definition of parent as the biological parent or parent with whom the child resides. "Educators must recognize that a student's most important *psychological* parent(s) may not be synonymous with residential biological parent(s) and that all of the parental figures have the *potential* to contribute to the student's development in school" (Crosbie-Burnett & Skyles, 1989, p. 61).

2. Think about parental involvement as many dimensions on a continuum versus dichotomous categories of involved or uninvolved. Parents who monitor their children's homework, for example, would not be considered "involved" by most school definitions yet this is a significant message of concern and values to children.

3. Adopt a perspective that assumes it is the responsibility of the community, not just biological parents, to raise children.

SUMMARY

Demographic projections indicate that the majority of children in the United States will reside in either single-parent or stepparent homes. Dominant social attitudes view these homes as deficient when contrasted with stable, intact families. Recent large-scale studies support this perspective with data indicating that *on the average* children from single-parent and stepparent homes do not do as well on a variety of outcomes when compared with peers in harmonious intact homes. It is important to bear in mind, however, that differences, although often statistically significant, are frequently practically insignificant, particularly when socioeconomic status is controlled. Thus, the majority of children in these families, practically speaking, do as well as children in intact homes. Clearly they do better than children in conflictual intact homes.

The fact that differences in child outcomes are obtained, however, between intact homes and non-intact homes, is cause for concern. When differences are large and significant, as with high school drop-out rates, concern is even greater. Multiple hypotheses have been proposed to account for these differences (including greater stress, differential socialization patterns, additional or deficient numbers of adults in family roles, differences in attachment related to biological-discrimination, and incomplete institutional support). However, both the diversity among single-parent and stepparent families as well as the complexity and multiplicity of variables that contribute to resilience and vulnerability make simple equations inappropriate. As with intact homes, a consideration of risk factors for children, regardless of family form, appears more appropriate than an assumption of risk inherent in family structure. Alternatively, family structure can be expected to influence family processes; thus, an appreciation of the common developmental challenges faced by single-parent and stepparent families facilitates prevention and sensitive intervention.

Schools and school psychologists can play an important role in promoting the viewpoint that single-parent and stepparent homes are normative and adaptive, not negative and deficient. Altering the contemporary social construction of reality, so strongly biased by the two-parent family of the 1950s, is, however, challenging. Therefore, this chapter concludes with a recent, simple proposition for the 1990s from syndicated columnist Ellen Goodman (1994). *Every American child should be born and raised in a three-parent family.* Goodman notes that a three-parent family would allow one parent to serve as primary caretaker at any instance given the necessity of two parents working full-time to maintain an adequate standard of living. The three-parent family would permit greater division of labor as parenting becomes increasingly complex. For example, one parent could be Designated Chauffeur, another Designated Worrier, another Designated Emergency Back-up System, another Designated Homework Monitor. In fact, Goodman notes, why stop at three parents — four may be better.

In summary, for the family of the 1990s, even the common social ideal of the intact family with two parents is not enough. As such, the socially networked single-parent family system and the multiple parent roles of the stepfamily system may reflect more evolved forms of the family. The challenge to schools and to school psychologists is to promote competent parenting and to provide support and acceptance to parents and children, regardless of family form.

ANNOTATED BIBLIOGRAPHY

Cohen, M. G. (1989). *Long distance parenting.* New York: New American Library.
Approximately half of divorced fathers have not seen their children in the past year. This book educates fathers regarding the importance of their involvement in their children's lives and provides tips on how to be an involved father regardless of geographic distance.

Furstenberg, Jr., & Cherlin, A. J. (1991). *Divided families: What happens to children when parents part.* Cambridge, MA: Harvard University Press.
This is a user friendly summary of the intervention implications of research on the effects on children of divorce, single-parenting, and remarriage. It is well-researched and authoritative but also clearly written without jargon. As such it is very useful background reading for both professionals and parents.

Grief, G. L. (1990). *The daddy track and the single father.* Lexington, MA: Lexington Books.
This is a self-help book for single fathers based on an updated survey of 1,100 fathers raising children alone. It provides both a view of characteristics of this growing population and information useful to single fathers. Chapters address common myths, running a household, parenting children, balancing work and family, conducting one's social life, getting along with the noncustodial mother, dealing with the courts and child support and joint custody, and fatherhood after death of a spouse.

Kissman, K., & Allen, J. A. (1993). *Single-parent families.* Newbury Park, CA: Sage Publications.
This book written primarily for professionals provides a comprehensive discussion of the heterogeneity of the single-parent family. Chapters are devoted to mother-headed families, ethnic families, adolescent parents, single-father-headed families, and noncustodial parents. Specific suggestions for intervention are provided. This book is unusually sensitive in discussion of issues of gender, ethnicity, race, and social class. As such, it is an invaluable resource on both single-parent families and professional cultural sensitivity.

Best Practices in Working with Bilingual Children

Emilia C. Lopez
Queens College, City University of New York

OVERVIEW

This chapter highlights best assessment and intervention practices for school psychologists working with bilingual students. It is also designed to heighten the awareness and sensitivity of school psychologists to students with linguistic and culturally different backgrounds.

The provision of assessment and intervention services for bilingual students is approached from a wide perspective; several factors that can influence how these students function in schools are examined. Those factors include internal or student-centered variables such as the student's language, cognitive, achievement, and socioemotional functioning as well as external variables such as the impact of culture, the instructional environment, and the classroom setting.

Recent statistics indicate that 5.3 million school-aged children in the United States enter school speaking a language other than English (Children's Defense Fund, 1989). Estimates for the 21st century indicate that the number of language minority children, including bilingual children in America's schools, will continue to rise.

Bilingual children live in homes where a language other than English is used either continuously or intermittently. The language proficiency profiles of these children may vary depending on their history of second language acquisition and the contexts in which they use each language (e.g., school vs. home).

Bilingual students may come from a multitude of cultural backgrounds and practices (Lynch, 1992). Although many culturally different families adhere to values and customs very close to those followed in the homeland, others may integrate into their repertoire some of the practices and values of the host culture while retaining some or many of their traditional patterns.

Children from bilingual homes may face a number of challenges including the severance of family ties and friendships as a result of migration; acculturation conflicts stemming from the clash between the family's more traditional values and the children's higher rate of acculturation into the host culture; higher levels of poverty associated with minority populations; and cultural conflicts resulting from subtle as well as major differences between the children's cultural values and those of the new adopted culture (Esquivel, 1985).

Bilingual students may encounter a number of educational barriers that can influence their performance in schools. These educational barriers may include prejudicial racial attitudes, intolerance to linguistic and cultural differences, lower levels of expectations from school professionals, a lack of access to adequate or higher level educational services due to tracking, and the implementation of policies and regulations insensitive to the needs of culturally different students (e.g., implementation of rigid assessment policies; Cummins, 1989).

BASIC CONSIDERATIONS

The Bilingual Child Within the Context of Language

Working successfully with bilingual children requires that all assessment and intervention practices should be based upon a well-developed knowledge base of first- and second-language (L1 and L2, respectively) development. Among the factors that need to be considered when interpreting assessment data are

1. The students' stage of L2 acquisition.

2. The students' language backgrounds (e.g., years of exposure to the English language, academic vs. informal exposure to L2).

3. The quantity and quality of exposure to L1 and L2.

4. The level of proficiency of L1 at the time L2 was introduced.

5. The age of the child at the time of L2 acquisition.

6. Personality factors (e.g., introversion vs. outgoing personality).

7. Motivation for learning L2 (e.g., internally vs. externally based).

8. The social distance between the student's culture and the culture of L2.

The planning and implementation of interventions for bilingual students must also be based on the knowledge of theory and research in language development, L2 acquisition, and effective language strategies. Some of this basic knowledge includes

1. The most effective strategies to help bilingual students learn L2 incorporate activities where language is used within natural, meaningful interactions.

2. "More language" (i.e., more English) is not better; what is important is exposure to comprehensible input in L2.

3. Bilingual children can develop high levels of literacy and proficiency in both languages.

4. High levels of proficiency and literacy in L1 can facilitate learning L2 because of the common underlying proficiency or interdependence across languages which facilitates the transfer of knowledge from one language to the other. (Cummins, 1984)

The Bilingual Child Within the Context of Culture

Culturally different families may differ from nonminority families along a number of complex variables that interact dynamically and may result in numerous cultural patterns or variations. (For a discussion of best practices in working with culturally different families, see the chapter by D. P. Flanagan and A. H. Miranda in this volume.)

According to Lynch (1992), culturally different families may differ in terms of their family composition; primary caregivers; childrearing practices; sleeping and eating patterns; response to disobedience and aggression; perceptions of disability, health, and healing; language; religion; communicative interaction styles; and help-seeking behaviors. These cultural characteristics and differences should be examined in the context of how they influence the students' functioning within assessment and classroom situations, schools, families, and communities. In planning and evaluating interventions, careful consideration should also be given to the benefits of incorporating activities, interaction styles, and instructional sequences that match the students' cognitive, emotional, and behavioral styles (Tharp, 1989).

The Bilingual Child Within the Context of the Classroom Setting

Bilingual children's poor academic achievement and behavioral difficulties are frequently, but inappropriately attributed to two factors: their lack of English language skills and their "culturally deficient" backgrounds (Cummins, 1989). School professionals' perceptions of bilingual children as poor academic achievers — and as language and culturally deficient — frequently result in referrals for special education assessment (Cummins, 1984). The special education assessment process currently employed in schools is student-oriented with assessment procedures geared towards identifying the internal or student-centered factors that have resulted in poor academic and behavioral functioning.

Recent trends in school psychology and special education emphasize a wider perspective or ecological model of assessment that views the student as part of many dynamically interacting systems which have a direct effect on students' performance in classroom situations (Cortes, 1986). Within this wider perspective, school psychologists can explore bilingual children's functioning in the areas of cognition, language, achievement, and socioemotional skills (i.e., internal variables) while also examining how instructional environments and classroom characteristics influence the bilingual students' behaviors and learning process. Information collected at the internal and external levels can be used to plan and implement interventions targeted at multiple sources (e.g., students, parents, teachers), settings (e.g., home, school), and situations (e.g., instruction, classroom management).

BEST PRACTICES IN THE ASSESSMENT OF BILINGUAL CHILDREN

Student-Centered Assessment

Bilingual children should be assessed by school psychologists who (a) are proficient in two languages; (b) have the prerequisite knowledge and skills in the nonbiased assessment of language proficiency, cognition, academic functioning, and socioemotional functioning; and (c) have intimate knowledge with the children's cultural backgrounds.

School psychologists working with bilingual students must maintain a culturally sensitive stance throughout all assessment activities by examining (a) the characteristics of culturally different individuals and families (i.e., the shared ideas, concepts, behaviors, and beliefs of a given cultural group); (b) the cultural values and practices that individual bilingual children adopt from their native culture and modify as a result of contact with the majority culture; and (c) the processes by which these cultural values and practices impact on bilingual children's functioning in the areas of cognition, language, thinking, learning, and socioemotional functioning.

Overall, normed instruments are not recommended in the assessment of bilingual children for a number of reasons including:

1. Norms are usually limited to small samples of minority children with the majority of children represented being of nonminority, middle class backgrounds.

2. Norming procedures routinely exclude students with limited English proficiency, a population of students frequently assessed by school psychologists.

3. Test items tap information that minority children may not be familiar with due to their linguistically and culturally different backgrounds.

4. Testing formats do not allow examiners the opportunity to provide feedback or to probe into the children's quality of responses.

5. The tests' scoring systems arbitrarily decide what are the correct responses based on majority culture paradigms.

6. The standardized testing procedures assume that the children have appropriate test-taking skills.

All of these criticisms are frequently cited as possible sources of bias in assessing bilingual students with continued debate as to the basis and evidence for bias (Reynolds & Kaiser, 1990).

Translated tests are often cited as an option because of the lack of instruments to assess children in languages other than English. However, this practice is strongly discouraged due to the inherent problems in translating test items. Difficulties in translating entail vocabulary and concepts that cannot be directly translated from one language to another, differences in dialects that can result in the same word being translated into several words in the other language, and concepts that change meaning once translated into a different language. Clearly, all these problems inherent to the process of translation render translated tests invalid as content changes may result in items that measure constructs and knowledge different from what was originally intended.

Alternative procedures for evaluating bilingual children include the collection of data from numerous sources (e.g., parent, children, school personnel) and the use of multiple procedures such as informal tasks, observations, interviews, checklists, and rating scales. Throughout the use of all these measures, school psychologists must proceed cautiously while attending to the students' familiarity with the content of the tasks and the test-taking skills they require.

Assessment of language proficiency. The assessment of language proficiency involves examining the bilingual student's expressive and receptive language skills in interpersonal as well as academic situations. Language proficiency tests for bilingual children are scarce and the few that are available are considered inadequate because of a lack of validity and reliability, a tendency to measure discrete aspects of language, and the use of arbitrary cutoff scores that vary from test to test (Mattes & Omark, 1984).

Among the practices recommended are parent, children, and teacher interviews to explore the history of language use, language development, and language background. Informal questionnaires may be helpful in collecting language-background data (for a sample of a language-background questionnaire useful with parents and teachers, see Payan, 1984). It is also important to collect language samples during informal situations (e.g., play, conversations) as well as in more formal academic tasks (e.g., classroom discussions). (See Prutting, 1983, for the assessment of language proficiency through language samples.)

Because language use and proficiency can vary along many dimensions, observations are also recommended across different languages (e.g., L1 and L2), situations (e.g., small group vs. large group), settings (e.g., classroom vs. school yard), topics (e.g., talking about math vs. talking about food), contexts (e.g., home vs. school) and individuals communicating with the assessment subjects (e.g., peers, adults, family). According to Mattes and Omark (1984), observations can be used to examine how bilingual children use their first and second languages to (a) comment on their own actions and the actions of others; (b) describe experiences; (c) recount events sequentially; (d) maintain topics; (e) answer questions; (f) request information, attention, clarification, and action; (g) express feelings and needs; (h) describe plans and solutions; and (i) support viewpoints.

Overall, all language proficiency tasks should be interpreted taking into consideration the following issues:

- As children are exposed to L2, they may demonstrate a loss of receptive and expressive language skills in L1. Thus, less developed skills in L1 may be due to the normal second language acquisition process and not to language disabilities.
- Bilingual students' proficiency may vary depending on the context in which the language is being used. For example, some bilingual children are well able to communicate in both languages in interpersonal situations but are more proficient in L2 within academic situations.
- Language proficiency includes Basic Interpersonal Communicative Skills (BICS) and Cognitive Academic Language Proficiency Skills (CALPS; Cummins, 1984). BICS entails the use of language during context-embedded, interpersonal situations whereas CALPS involves the use of language dur-

BEST COPY AVAILABLE

ing context-reduced, academic situations. The L2 acquisition research indicates that BICS takes approximately 2 years to develop in L2 whereas CALPS takes 5 to 7 years. Language proficiency data based on tasks that assess BICS (e.g., observations during play activities, language samples during informal conversations) should not be used to determine bilingual children's ability to use language in cognitively demanding, academic situations. CALPS should be determined through tasks that assess bilingual students' abilities to use language in academic situations (e.g., observations of academic behaviors, collection of language samples in academic situations).

Assessment of intelligence. The intellectual assessment of bilingual children is perhaps the most debatable area in the assessment arena with supporters arguing that there are no empirical data justifying the critics' call of bias (Reynolds & Kaiser, 1990). Critics, however, question the existing research on bias because of methodological flaws failing to consider the effects of L2 on test scores (Figueroa, 1990a). Critics also point to inherent flaws in cognitive measures due to problems in defining and understanding (a) the construct of intelligence, (b) the constructs represented within the test items, (c) the processes underlying the test items, and (d) the skills assessed by the cognitive tasks in those tests (Reynolds & Kaiser, 1990). Perhaps one of the strongest criticisms is that cognitive tests fail to measure intellectual functioning and instead assess bilingual children's language ability. Also, intellectual measures may stress a set of cognitive processes relevant primarily to children from nonminority populations (Armour-Thomas, 1992). Thus, they fail to capture the idiosyncratic ways in which culture shapes an individual's thoughts, organization of knowledge, cognitive strategies, and learning modes used to solve complex intellectual tasks. Despite strong opposition, school psychologists continue to use cognitive tests in assessing bilingual children. Questionable practices such as the use of adjusted IQ scores and tests standardized in other countries also persist but are not recommended because of their lack of validity with bilingual students.

Dynamic assessment procedures such as Feurstein's Learning Potential Assessment Device are often discussed as one alternative to validly measure cognitive function (Duran, 1989). Dynamic assessment procedures are designed to involve assessment subjects in test-teach-test approaches that evaluate children's cognitive deficiencies and examine under what learning conditions those deficiencies can be overcome. However, a lack of empirical evidence attesting to their validity continues to render dynamic assessment procedures as questionable with bilingual students.

Other alternative procedures include nonverbal tests and developmentally based tasks. Nonverbal tests should be used with caution as they usually assess a narrow set of cognitive strategies and the performance of bilingual students may still be dependent on their familiarity with test-taking skills and with the test content. Piagetian tasks such as the Cartoon Conservation Scales (DeAvila, 1977) are also a viable alternative but they too are limited in terms of the range of skills they evaluate.

Recent reviews of the literature are calling for new forms of cognitive assessment instruments based on the culturally sensitive models of Vygotsky and Cecic as well as on the multidimensional models of Gardner and Sternberg (e.g., Armour-Thomas, 1992). There is also a call for assessment models that explore individual cognitive functioning within the context of culture and experience. The adoption of such models would have serious implications for the training of school psychologists as programs would need to emphasize alternative assessment theories and practices.

Assessment of academic functioning. Currently available academic measures have questionable validity with bilingual populations because of basic flaws (e.g., norms inappropriate for minority student populations, rigid standardization and scoring systems) common to normed tests. As a general rule, academic measures in English tend to measure bilingual students' language proficiency in English and fail to assess achievement or knowledge of academic content (Figueroa, 1990a). Although some instruments are available in other languages, the validity of their results are usually limited because many bilingual children have never received instruction in their native or home language and the test results are confined to that interpretation. Other strong criticisms directed at academic tests include their lack of connection to the curriculum of the students, their tendency to assume that all children have the same background knowledge, and their emphasis on content unfamiliar to culturally different children.

Alternative procedures include Curriculum Based Assessment activities such as informal reading inventories, error analyses, and task analyses that use the students' curriculum materials as the basis of the assessment. Criterion-referenced tests, either publisher-constructed or self-made, can also be helpful when attempting to establish accomplished and future academic goals. Test-teach-test dynamic approaches may be most valuable when the assessor uses tasks and materials directly related to the students' academic functioning rather than more cognitively based procedures (e.g., Feurstein's Instrumental Enrichment program), which are less pertinent to the classroom setting and demonstrate limited validity (Duran, 1989). Curriculum Based Measurement (CBM) procedures to measure bilingual students'

English language skills are now emerging and merit serious consideration as tools to measure these students' academic functioning (Baker & Good, 1993). Currently, the use of portfolio assessment is advocated for bilingual students because of its emphasis on examining students' permanent products (Canales, 1993). However, its validity has not been established and its usefulness largely depends on the kind of work included in the portfolio and the criteria used to evaluate them.

Overall, whichever alternative procedures are used to measure bilingual students' academic performance, school psychologists must give careful consideration to the interaction between the content of the procedures and the student's background. Bilingual students' performances on academic tasks are largely dependent on the type of previously established knowledge they bring to the testing situation. Thus, asking comprehension questions after they read a story they know little about limits their ability to understand the story and to respond appropriately to the questions in either language.

Assessment of socioemotional functioning. In general, there is a lack of emphasis on social-skills-assessment issues in the literature pertaining to bilingual students. Many unanswered questions remain concerning how linguistic and cultural differences affect bilingual students' ability to function adaptively in home, school, and community situations. Currently available instruments to measure adaptive behavior are mostly normed with nonminority samples and scored using majority-culture behavioral expectations, rendering them inappropriate for use with bilingual and bicultural students. In addition, many of these measures tend to be limited because they emphasize data collection in one setting, either home or school, and fail to examine the potential differences in children's performances across settings and cultural milieus (Scott, Mastenbrook, Fisher, & Gridley, 1982).

School psychologists are advised to use a variety of formal and informal techniques that include interviews, behavioral observations, self-reports, and rating scales to examine bilingual students' functioning across a number of settings (e.g., school, home, community). Interpreting the results derived from these measures may be facilitated by examining bilingual students' social skill deficits in terms of (a) their familiarity with the majority culture's behavioral expectations, and/or (b) the acculturation conflicts that may interfere with the student's ability to perform adequately within various social situations. Throughout the process of assessing social skills, school psychologists can minimize bias by comparing the performance of individual bilingual students to other children of the same age, socioeconomic level, and linguistic and cultural backgrounds.

The use of projective techniques to assess children's emotional functioning has generally been criticized for its lack of validity in intervention situations (Moran, 1990). Also, little is known about its usefulness with bilingual children because of a lack of research with this population. The few empirical studies currently available, comprised mostly of adult with only a few children's samples, have shown that minority subjects tend to perform differently than nonminority subjects on a number of projective measures. In general, minority subjects tend to score higher on items that typically indicate pathology. Studies with bilingual subjects also indicate that individual responses to projective stimuli can vary depending on the languages the subjects are using with different languages acquiring different affective meanings. Overall, these studies imply that projective techniques developed and normed with nonminority subjects fail to capture the influence of language and culture on bilingual children's belief systems; symptom manifestations; defensive styles; and patterns of coping with anxiety, depression, fear, guilt, and anger.

The projective assessment of bilingual children must be approached cautiously while taking into account the specific cultural and linguistic characteristics of each individual. A projective instrument that appears to have promising validity and reliability properties with Hispanic children is the Tell-Me-A-Story Test or TEMAS (Constantino, 1986), a projective technique which uses stimulus cards representing minority characters in urban settings and within culturally relevant themes. Based on the accumulated empirical support for TEMAS (e.g., Constantino & Malgady, 1983), the development of culture-specific tests seems a promising alternative to measure bilingual students' empirical functioning.

Assessment of the Classroom Situation

The traditional student-centered assessment orientation has been criticized for its failure to view bilingual children within the context of an array of other systems that interact dynamically and have a direct impact on bilingual children's learning and behaviors (Cortes, 1986). Some of those systems include the family, the community, and the instructional and classroom environments. Although it is beyond the purpose of this chapter to address each of the systems that impact on bilingual children's functioning in schools, the instructional and classroom environments are discussed as important components to examine within the assessment process.

Assessment of the instructional environment. The main purpose of assessing the instructional environment is to examine the appropriateness of the tasks and methods used in the instruction of bilingual children. School psychologists involved in assessing the instructional environments of bilingual children can base their assessment on the following questions:

- Are the appropriate languages being used for instruction?
- Is the level of the language used in the instructional tasks comprehensible to the student?
- Is language and content context-embedded?
- Are the classroom materials appropriate for the language and academic skills of the students?
- Do the students have the sufficient background knowledge to understand the content of the instructional materials?
- Can the students relate to the content of the instructional materials from a cultural perspective?
- Are instructional activities and materials used for the purposes of developing literacy skills?
- Is the curriculum being adapted to the needs of exceptional bilingual students?

Classroom observations, interviews, task analyses, and examination of students' permanent products (e.g., tests, assignments, homework) can be used to determine the effectiveness of the instructional materials and the need to modify existing instructional procedures.

Assessment of the classroom setting. The literature on classroom interactions, management, and organization is extensive but lacks emphasis on issues relevant to bilingual students. However, there are empirical data to support the hypothesis that teachers' expectations of minority students are related to the types of interactions occurring in classrooms: Low-achieving minority students tend to receive less positive feedback and less attention (Cummins, 1984). This line of research has also demonstrated a relationship between teacher expectations, differential teacher behavior, and minority students' low academic achievement in the classroom. There is also much concern that interactions in most classrooms, including bilingual classrooms, are described as teacher centered and with little student input (Ramirez, Yuen, & Ramey, 1991). Other empirical research exploring culturally relevant variables within classroom settings indicate that many language minority students perform poorly academically and behaviorally when classroom interventions do not match the cultural backgrounds of the students (Tharp, 1989).

Baca (1984) recommends that classroom interactions and management strategies should be evaluated in the context of (a) the bilingual students' cultural perspective and (b) the potential effects of using biased behavioral and classroom management strategies. School psychologists involved in assessing classroom settings can use data from observations as well as teacher and student interviews to explore the following questions:

- Are there cultural disparities between the interactional styles of the teachers and bilingual students?
- Is the classroom managed using strategies sensitive to students' cultural differences in communication, attitudes, and values?
- What are the teachers' expectations towards the bilingual students?
- Are cultural differences recognized and valued in the classroom?
- Are the rewards and incentives used valued within the cultural backgrounds of the bilingual students?

Concluding Comments on Best Practices in Assessment

Assessing bilingual students is a time-consuming process that strives to explore language and cultural issues while collecting data from numerous sources in various contexts and through a variety of techniques. Throughout the assessment process, consideration should be given to the establishment of strong collaborative relationships with teachers and other school professionals. Assessment conducted through collaborative efforts can facilitate the process of data collection and establish a cooperative environment conducive to the planning and implementation of appropriate interventions (Conoley & Conoley, 1992).

BEST PRACTICES IN PLANNING AND IMPLEMENTING INTERVENTIONS FOR BILINGUAL CHILDREN

Planning and implementing effective intervention strategies for bilingual students is contingent on two factors. First, all assessment data collected should be directly linked to interventions by using assessment techniques that help identify specific intervention goals. Second, all interventions should be monitored continuously to establish their effectiveness and the need to make specific modifications.

Choosing the Language of Intervention

The issue of which language to choose for bilingual students' interventions is complicated and sparked by controversy. Factors to consider in determining the language of intervention include:

- The student's level of proficiency in the two languages.
- The student's age (e.g., high school students with low proficiency in English may need to receive vocational training in their native language).
- The student's length of time in the country.

- Type and severity of the handicapping condition (e.g., severely mentally retarded children may need to receive services in their native language).
- Cognitive demands of the subject matter taught.
- Programs available.
- Parent and student preferences.
- Local and national policies.
- Availability of bilingual personnel.
- Student performance within a given language (Ortiz, 1984).

Instructional Programs for Bilingual Students

The three instructional programs generally available for bilingual students include bilingual transitional, bilingual maintenance, and English-only programs. Each is usually accompanied by English as a Second Language (ESL) instruction. ESL instruction generally entails a variety of strategies to improve the English-language skills of L2 speakers (for a review of the literature on bilingual education and ESL see Wong-Fillmore & Valadez, 1986).

As their names imply, bilingual transitional and bilingual maintenance programs provide instruction in both English and the primary language of the students. However, the language models used within and across programs may differ. They include:

1. The alternate-days approach whereby each of the two languages is used every other day.

2. The alternate-subjects approach in which one language is used in a set of subjects while the second is used in a different set of subjects.

3. The phased approach with L2 being phased in progressively.

4. The preview-review technique in which the lesson is previewed in one language and expanded in the other language.

5. The translation approach whereby information is given in one language and translated to the other on a continuous basis.

6. The functional approach whereby translations are used only when the students are having difficulty grasping concepts and the teacher wishes to provide clarification or background information (Wong-Fillmore & Valadez, 1986).

The foundation for bilingual programs rests in the empirically supported, common underlying proficiency principle. This principle states that first and second language skills are strongly interdependent and that instruction in L1 is developing not just the first language but also a deeper conceptual and linguistic proficiency transferrable to L2 (Cummins, 1984). Thus, a student who learns and understands the concept of "democracy" in L1 will be able to transfer that knowledge to L2.

Despite their commonalities, there are some major differences between bilingual transitional and maintenance programs. Bilingual transitional programs aim to develop English language proficiency and to transfer bilingual students to English monolingual classes after 2 or 3 years of instruction. Within transitional programs, the students are instructed in two languages until they can speak sufficient English to go into an English-only class. In contrast, bilingual maintenance programs have the goal of developing literacy and language skills in both the primary language and English. Thus, students in maintenance programs stay in bilingual classrooms for a longer period of time and continue to learn in both their primary and secondary languages.

The third type of program, the English-only program, entails placing students in English-speaking classrooms without any bilingual support. In the United States, these programs are sometimes referred to as immersion programs. However, contrary to popular belief, English-only programs are substantially different from the Canadian immersion programs which aim to develop bilingual skills in French and English by initially immersing the students in L2 and eventually introducing them to instruction in both languages (Cummins, 1984).

Bilingual maintenance programs have received strong opposition despite empirical evidence demonstrating that *quality* programs result in higher achievement for bilingual students (Ramirez et al., 1991; Wong-Fillmore & Valadez, 1986). The school psychology literature is noticeably devoid of discussions related to bilingual education. However, in the author's experience, practicing school psychologists constantly struggle with their assumptions and questions about bilingual education issues. Overall, school psychologists involved in recommending and planning programs for bilingual students should consider all the variables discussed in the previous section (i.e., Choosing the Language of Intervention), maintain a flexible attitude, and keep in mind that a position such as "children are unable to learn within bilingual milieus" negates the tremendous potential of the human organism to learn under a variety of conditions and circumstances.

Instructional and Classroom Interventions

The literature offers a variety of interventions recommended for bilingual children. Yet the scarcity of empirical studies validating the effectiveness of many interventions often renders those recommendations questionable. Some data are available to support general strategies reported as effective with bilingual children. According to Ortiz (1984, pp. 85–86), the process of L2 acquisition is facilitated for *all* second language learners by activities that:

1. Maximize student exposure to natural communication.

2. Focus on the message being conveyed, not the linguistic form of the message.

3. Incorporate a silent period at the beginning of the instructional program so that students can listen to the second language without being pressured to speak it.

4. Encourage and create situations in which students can interact with native speakers of the language.

5. Use concrete references to make the new language understandable to beginning students.

6. Devise specific techniques to relax students and to protect their egos. Less anxious, more motivated, more self-confident students experience greater success in second language acquisition.

7. Motivate students to learn.

8. Create an atmosphere where students are not embarrassed by their errors.

9. Do not refer to, or revert to, the students' native language when teaching the second language. To do so may create a situation in which the student, instead of focusing attention on the second language, simply waits for the teacher to repeat utterances in the native language. Under these circumstances, motivation for second language learning may be negatively affected.

Other strategies recommended for all bilingual children include the use of:

- Contextualized instruction that incorporates the students' experiences.
- Instructional sequences with meaningful interactions that facilitate comprehending the content of the material learned.
- Previously learned information to provide a bridge for students to learn new concepts and skills.
- Multicultural materials relevant to the students' backgrounds and experiences.
- Whole language and language experiences approaches that integrate writing, reading, and oral language activities.
- Peer teaching and cooperative learning activities that encourage student participation.
- Metacognitive (e.g., self-management, functional planning, advance organizers) and cognitive (e.g., note taking, inferencing, cooperation) strategies to facilitate the learning of language and content.
- A variety of writing activities that focus on learning clear communication as well as the mechanics of writing (e.g., punctuation, spelling).
- Thematic curriculum strategies that integrate the learning of language skills and content.
- Strategies that emphasize the use of higher order thinking skills (e.g., analyzing, synthesizing). (Cummins, 1984, 1989; Ortiz, 1984; Tharp, 1989).

Classroom environments conducive to learning for bilingual students have the characteristics of high on-task ratios with teachers who expect the children to succeed and achieve (Cummins, 1989). Dulay, Burt, and Krashen (1982) also recommend a low-anxiety classroom atmosphere where errors are expected and students are encouraged to question ideas and experiment with language. Rewards used in classroom situations, whether intrinsic or extrinsic, should be motivating on the basis of the students' individual and cultural preferences.

Finally, Tharp (1989) recommends integrating activities, interactions, and organizational structures that match the students' cultural backgrounds. To illustrate, Hawaiian children have been found to frequently engage in several types of classroom interactions including (a) high levels of seeking attention from peers, (b) low levels of seeking attention from teachers, and (c) "talk-story" sequences characterized by the children co-narrating and overlapping in conversations with adult narrators. According to Tharp, all those behaviors are based on Hawaiian cultural traditions in which cooperation, peer assistance, and sharing of experiences in story telling are valued behaviors. In classrooms with low-achieving Hawaiian children, the emphasis on cooperative activities, small-group classroom activities, and lively discussions have resulted in significantly higher academic achievement. In comparable programs with Navajo children, the introduction of classroom discussion patterns that emphasize the Navajo cultural traditions of turn-taking, a slow pace of talking, and longer discussions have also resulted in higher achievement and greater student participation.

Interventions for Social Skills and Emotional Functioning

In general, the school psychologist involved in providing social skills training to bilingual students is once again left with no specific guidelines as to how language and cultural variables affect the process of social skills training. Obviously, any social skills intervention program should be planned and implemented taking into account the social skills deemed appropriate within the students' cultural backgrounds.

Counseling services may be appropriate when bilingual students demonstrate social or emotional difficulties that interfere with their classroom functioning. A cross-cultural counseling perspective is recommended for school psychologists working with bilingual students. Cross-cultural counseling is especially relevant when language and cultural issues are influencing bilingual students' performance in school. According to Esquivel and Keitel (1989), bilingual students may struggle with acculturation issues, ethnic identity confusion, and culture shock reactions that can impact on classroom functioning. In addition, bilingual students may experience high levels of stress related to learning a second language and to racist attitudes within schools and communities. Among the culturally sensitive techniques recommended in the literature are (a) ethnotherapy whereby emphasis is placed on helping individuals to develop a positive sense of ethnic identity (Klein, 1976, cited in Esquivel & Keitel, 1989), (b) cuento therapy in which folk stories are used to explore cultural identity and ego development (Constantino, Malgady, & Rogler, 1986), and (c) the use of toys and materials that reflect the students' cultural and linguistic backgrounds. Group counseling approaches may also be appropriate but their usefulness must be evaluated for children whose cultural backgrounds do not encourage self-disclosure with individuals outside of the family structure. Finally, all social skills training and counseling activities should be delivered in the students' primary or most proficient language to facilitate the communication process.

Concluding Comments on Best Practices in Interventions

Planning and implementing effective interventions for bilingual students requires a cooperative and collaborative working relationship between school psychologists, teachers, and other school personnel. As such, consultation may facilitate the process of working with school personnel involved in delivering interventions to bilingual students. Consultation is defined as a collaborative process in which consultants such as school psychologists can help consultees (i.e., bilingual teachers, ESL teachers, as well as regular education and special education teachers instructing bilingual students) with students' classroom difficulties (Conoley & Conoley, 1992). Cross-cultural models of consultation are beginning to emerge in the literature and focus on delivering consultation services within a linguistic and culturally sensitive context (Lateer & Curtis, 1991; Lopez, 1993).

Intervention activities must also be framed within a home-school collaboration partnership. Empirical data are available demonstrating that bilingual students achieve in programs emphasizing parent involvement in (a) curriculum planning, (b) school organization, (c) classroom participation, and (d) home activities that promote literacy in the native language (Cummins, 1989). Consulting with parents may also be beneficial in exploring with the family the appropriateness of the recommended interventions from a cultural perspective.

The Use of Interpreters During Assessment and Intervention Activities

The shortage of bilingual school psychologists has resulted in the frequent use of school interpreters. Little is known about the effects of using interpreters because of the lack of research in this area. However, there are some potential problems that school psychologists should keep in mind.

Preliminary findings of a recent study indicate that inexperienced and untrained interpreters can make errors in the process of translating IQ test questions from English to Spanish (Lopez, 1994). Many of these errors consist of substantial changes in the content and meaning of the test questions. School psychologists using interpreters will most likely not be aware of such errors and the ultimate outcome may be erroneous interpretations of assessment data and inappropriate classifications.

Well trained interpreters can certainly be an asset during assessment and intervention activities but most school interpreters lack training in a number of important areas (Lopez, 1992). Even if well trained interpreters are available, differences across languages as well as dialectical differences within languages (e.g., differences in dialects between Spanish speakers from Puerto Rico, Cuba, Santo Domingo, etc.) can still make the process of translation difficult and substantially change the validity of the measures and procedures used in assessing bilingual students.

The use of interpreters during intervention activities can hinder the establishment of rapport (Esquivel & Keitel, 1989). Their use adds another layer to the complexity of delivering intervention services, complicates issues of confidentiality and trust, and can create barriers in the communication of affect and in the establishment of the working alliance so necessary to the process of working with children and families.

In general, the process of working with interpreters during assessment and intervention activities is risky, speculative, and plagued with conjecture. They should therefore, be the absolute last resort. School psychologists who find themselves in situations where they must work with interpreters should adhere to the following best practices (Figueroa, 1990b; Langdon, 1985; Lopez, 1992):

- Choose interpreters who have prior experience as school interpreters, high proficiency in both languages, a high level of education, and are familiar with the field of education and special education and with the student's cultural and linguistic background.

- Train interpreters in issues related to test administration, assessment of exceptional children, and the special education process (e.g., due process, IEP meetings).
- Provide interpreters with the opportunity to translate written documents prior to meeting with parents (e.g., IEPs).
- Encourage interpreters to ask questions as the testing session or meeting is occurring.
- Prior to actual assessment sessions, provide interpreters with time to ask questions about test procedures and to discuss testing procedures and details related to the student's background (e.g., place of birth).
- During testing sessions or meetings, (a) speak in short, simple sentences; (b) avoid idioms, metaphors, or colloquialisms; (c) use specific terms and avoid jargon; (d) allow the interpreters time to translate all messages; and (e) do not speak to your colleagues while interpreters are in the process of translating.
- After the testing session or meeting, discuss any difficulties encountered during the process (e.g., words that could not be translated), and explore cultural factors that may have influenced the child's/parent's behaviors.
- Do not use interpreters for on-the-spot translation of test questions. Instead, rely on validated test translations.
- In psychological reports, provide details on how the interpreter was used and in which contexts. Also, report all data collected through interpreters in qualitative format and use extreme caution when interpreting the results obtained.

SUMMARY AND CONCLUSION

School psychologists involved in delivering assessment and intervention services must work in the context of examining the language and cultural issues that have a direct impact on bilingual students' performance in classroom situations. The performance of bilingual students should also be examined within the context of the instructional and classroom variables that inhibit or promote appropriate classroom performance. Many unanswered questions remain concerning the best assessment and intervention practices for bilingual students but some general guidelines can be followed to minimize bias during assessment and intervention activities. Those guidelines are best implemented when school psychologists become directly involved in advocating for bilingual children and substantially change existing school practices that limit bilingual students' potential to achieve and succeed.

Best Practices in Program Planning for Children Who Are Deaf or Severely Hard of Hearing

Susan Vess
University of Southern Maine

Laura Douglas
Colorado School for the Deaf and Blind

OVERVIEW

Since the implementation of Public Law 94-142 (Education for All Handicapped Children Act of 1975), many children who are deaf or severely hard of hearing (HOH) have been educated within their local public schools, generally through day classes within special education. Their schooling has also been affected by the educational reform movement of the 1980s, including its emphasis on academic achievement and other instructional modifications. However, issues related to efforts in integrating them into general education with the support of interpreters are complex.

According to Mertens (1989), proponents of mainstreaming claimed that integration provided children who are deaf or HOH with the opportunity to acquire social and communication skills needed to participate in the hearing community. Conversely, others supported a full range of educational options saying that mainstreaming isolated these children from members of the deaf community. Neither argument was supported by research, although observation indicated that proximity alone with hearing children did not translate directly into social interaction.

In 1988, the U.S. Presidential Commission on Education of the Deaf made the following observation about the impact of integration on children who are deaf and HOH:

> Of the children mainstreamed, only about half actually experience any true integration, even on a part-time basis. Due to a lack of understanding of the nature and diversity of hearing impairment, the unique communicative, linguistic, and social needs of the deaf child have seldom been met appropriately, particularly in the mainstream setting, despite the Education of the Handicapped Act. LRE has too often been regarded as synonymous with mainstreaming; the regular classroom, even with supplementary aids and services, is often inappropriate. (p. 9)

The Commission went on to recommend "the Department of Education should refocus the least restrictive environment concept by emphasizing appropriateness over least restrictive environment" (p. 27). This controversy confused parents of children who are deaf or HOH as they attempted to choose the best educational programs for their children. Further, it clearly indicated that the education of these children is far more complex than choosing among service delivery options.

BASIC CONSIDERATIONS

Frequently, deaf individuals were the subjects of studies focusing either on the presumed negative consequences of deafness on development and behavior or on identifying the best means of teaching children who are deaf, especially finding strategies that promoted the acquisition of speech and language. Findings of these studies suggested that the supposedly marginal behavior and abilities of persons who are deaf or severely HOH isolated them from the hearing society. Multiple negative personality traits such as immaturity, impulsivity, egocentricity, rigidity, irresponsibility, and noncompliance were identified and said to typify these individuals. Additionally, people who were deaf or HOH were described as more concrete and less intelligent than hearing persons because they performed less well on standard intelligence tests. Thus, conclusions derived from conventionally designed research projects often reflected an all or none perspective in which deafness represented either an overwhelming disability or a variation of normalcy.

Traditional research methods which attempted to isolate the operation of specific variables rarely captured the complexity and diversity of deafness and its impact on the child who is deaf or HOH and his or her family. Moreover, as Leigh and Stinson indicated (1991), it was not unusual for the hearing community to expect people who were deaf to learn speech and speech reading and to conform to social and behavioral expectations of the hearing world. When deaf or HOH persons did not comply with these demands, they were viewed as unwilling to belong to the dominant community.

Recently, conclusions drawn from research not only affirmed the essential normalcy of deaf individuals, but also acknowledged that children who are deaf or HOH are shaped by their soundless environment. From this perspective, people who are deaf or HOH are normal, but their unique environments contribute important differences in the development of cognitive, linguistic, and social behaviors. Because deaf and hearing children are exposed to qualitatively and quantitatively different environments, it is both erroneous to equate difference with deviance and unrealistic to lose sight of the importance of deafness for the child and his or her family (Marschark, 1993).

The overly simplistic deviance and normalcy perspectives failed to recognize the uniqueness of each child who is deaf or HOH, the etiology of his or her deafness, the impact of any additional handicaps, the role of family dynamics, the input of the child's school and community, and the importance of tricultural issues if the child was also a member of a minority group. Further, there was minimal consideration of (a) the contribution of a child who is deaf or HOH to the family system, (b) the importance of the family's structure and values on the child's development, and (c) ways in which the child who is deaf or HOH was similar to and different from family members. It is now understood that synergy and reciprocity in family and interpersonal relationships as well as integration across cognitive, socio-emotional, linguistic, and communicative areas of development are more critical factors than deafness itself in determining outcomes for the child.

Social-emotional functioning and compensatory strategies for learning are often not included in the evaluations of the child who is deaf or HOH. In developing a quality evaluation of hearing children, the following 20 questions are central in the ongoing process of planning and evaluating a comprehensive educational program for every deaf or HOH child and helping parents explore their child's specific academic, social, emotional, and linguistic needs:

1. What are the student's personal, nonlanguage, and nonacademic strengths and skills?

2. How does the child interact with deaf and hearing peers and deaf and hearing adults?

3. How does she or her react to frustration in communication, ask for help, develop and display coping mechanisms?

4. What are the child's work habits?

5. Does the student feel successful in and enjoy school?

6. Does the student feel that he or she is placed in classes that are neither too easy or too difficult?

7. What are the child's favorite and least favorite classes?

8. What reasons does the child cite for these preferences?

9. Does the child have friends?

10. Who are the student's friends and how do they communicate?

11. What leisure and recreational skills does the child have?

12. In which recreational activities does she or he participate?

13. Are there others the student would like to participate in and what would it take to accomplish that participation?

14. What are the child's roles in the immediate and extended family and in the neighborhood and community?

15. How does the student feel about himself or herself?

16. What personal goals has the student set?

17. What is the family's perspective on the child's progress, strengths, and needs?

18. How does the interpreter perceive the child's progress and needs?

19. What are the child's skill levels in the various academic areas as measured by curriculum based assessment (CBA)?

20. What specifically is needed to maximize the child's socio-emotional development, enable participation as a valued member of the family and community, integrate the child into the deaf and hearing communities, and promote acquisition of social, communicative, and academic skills?

The primary goal of each deaf or HOH child's education is development of a host of positive attributes, including self-confidence, pride in oneself and one's accomplishments, responsibility, independence, and self-determination (Kessler-Grimes & Prichett, 1988). In 1988, the Colorado Department of Education (CDE) developed a service design checklist to help school psychologists design and evaluate the educational programs of deaf or HOH children and to ensure that the schools address each child's social, emotional, recreational, and communication needs. The 20 questions combined with the service design checklist identify the critical program components that support the successful education of the child who is deaf or HOH.

FIGURE 1. Service Design Checklist.

Have you considered:

Family School Partnership

- Providing emotional support to the family
- Providing information to the family on:
  - implications of hearing loss
  - importance of communication
  - assistive devices
  - functions and publications specific to hearing impaired individuals
- Providing skill training in:
  - speech, language, auditory skill development
  - sign language
  - hearing aid maintenance
  - behavior management

Learning Environment

- altering the student's physical environment:
  - room accommodations regarding noise, lighting, seating
  - captioned films and videos
  - assistive listening devices such as auditory trainers
  - a telecommunication device for telephone usage
  - flashing fire alarm
- Providing inservice training to all the student's teachers and peers
- Providing notetakers, interpreters, tutors; using a buddy system
- Providing specific teaching regarding rules and expectations

Communication

- Providing specific instruction in language development:
  - communication intent and appropriateness
  - language meaning and content
- Providing auditory training
- Providing training in speech production and refinement
- Utilizing manual communication

Instruction

- Utilizing a multisensory approach
- Teaching the exceptions of new concepts
- Assisting and limiting number of concepts to be learned
- Providing materials at appropriate reading levels
- Providing notetakers, interpreters, tutors, peer tutors, buddies
- Providing class outlines, vocabulary lists, class notes

Transition to Adulthood

- Providing information relating to independent living:
  - obtaining and utilizing interpreters
  - rights of a handicapped citizen
  - telling employers and others about your hearing loss and needs
  - hearing aids, TDDs, relay systems, assistive learning devices
  - counseling and community mental health services available
  - support groups for hearing impaired individuals
- Providing information, training, and experiences relating to career:
  - specific information on postsecondary educational facilities, vocational rehabilitation, centers of deafness, etc.
  - specific instruction on social skills, work habits, and work ethics
  - shadowing and specific instruction at job entry
  - exposure to jobs of other hearing impaired adults
- Providing information about recreation/leisure activities including social clubs for hearing impaired individuals

(... Figure 1, continued)

Development of Self

- Helping the student to understand him/herself, to share feelings, goals, etc.
- Encouraging and expecting the student to take responsibility for him/herself ... permitting failure as well as success
- Providing opportunities to learn about deaf culture and heritage
- Providing specific instruction in social skills

Note. From *Guidelines for Designing and Implementing Services* (pp. 14–15), by C. Amon, J. Sutera, C. Johnson, and C. Yoshinaga-Itano, 1988, Denver, Colorado Department of Education. Reprinted by permssion.

When designing an effective educational program for the child who is deaf or HOH, two additional points should be kept in mind. First, information about the deaf or HOH child's world and its impact on all facets of his or her life needs to be integrated with educational and social goals. Second, this child, like hearing peers, learns most effectively in naturally occurring conversations and social interactions and through modeling and context. From this information, the basic considerations for developing an effective program flow:

1. Select a program content that includes skills that a hearing child acquires indirectly through exposure to sounds coupled with experience.

2. Create experiential contexts for a deaf or HOH child isolated from regular interaction with deaf persons or fluent signers.

3. Evaluate how the child's development compares to that of a hearing child of the same developmental age.

4. Incorporate the observations, input, and preferences of the child and his or her parents.

Because eligibility for services for a child who is deaf or severely HOH rests primarily on acuity and other information provided by doctors, audiologists, and other professionals, school psychologists usually play a minimal role in its determination. However, they can be able advocates for the child and his or her family and knowledgeable participants in planning, evaluating, and modifying programs into which this child is placed. A willingness to incorporate the perspectives of parents, the child, and teachers into the educational plan is fundamental to the school psychologist's roles as child advocate, program planner, and evaluator.

BEST PRACTICES

Implementation of a program that allows each child who is deaf or HOH to participate in as many and varied environments as experienced by hearing peers constitutes the most fundamental recommendation (Colorado Department of Education, 1988). Because sheltering a child who is deaf or HOH does not promote acquisition of the skills, attitudes, and behaviors she or he will need as an adult, full participation in multiple environments must include the opportunity to learn from both success and failure.

Partnerships between Parents and Professionals

Historically, many parents of a deaf or severely HOH child felt that they were forced to grant parent surrogate status to schools for the deaf and that residential counselors and teachers played a large role in raising their child. Some parents believed that professionals usurped parental prerogatives and focused more on the child's test scores and audiograms than on the actual child (Morgan-Redshaw, Wilgosh, & Bibby, 1989). Others were frustrated by the limited number and types of programs available in the public schools because inadequate local resources prevented them from taking a more active role in raising their deaf or HOH child. Finally, many parents encountered deaf educators who argued that a particular teaching or speech/language strategy was the only method that guaranteed the parents' goal of enabling their child to speak and participate in the hearing community but found that their hopes were seldom realized. Thomas (1989) illustrated this point in her description of oralism: "Oralism is the philosophy and method dedicated to making deaf people as undeaf as possible. Parents rush to it because they are provided no alternatives to believing that being 'like hearing' is the only way of being" (p. 8).

Parents' competency and preferences were increasingly recognized by deaf educators as children who are deaf or HOH remained at home to be educated in day classes within the public schools. As the experts on their child who is deaf or HOH, and the primary agents in that child's socialization, parents were now expected to speak with decisive voices as the educational programs for their child were planned and implemented. However, the pressure for parents of a child who is deaf or HOH to assume advocacy and teaching roles often required them to put aside their own reactions and inclinations as they advocated for their child in the educational system and larger community. Additionally, Schlesinger (cited in

Lederberg, 1993) identified three contributors to parents' sense of powerlessness and frustration in raising a child who is deaf or HOH: (a) their inability to cure their child's deafness, (b) the deaf or HOH child's lack of responsiveness to the parents' normal communication in English, and (c) the intrusion of professionals into the expression of parental rights.

Research has clarified parents' feelings and perspectives about raising a child who is deaf or HOH. Parenting this child produces all the normal stresses associated with child rearing and then adds stressors such as learning about deafness, making choices about the child's education, and serving as intermediaries between the child and the hearing world. Parents gladly adopt greater decision-making power in the education of their child who is deaf or HOH but also describe the enormous fatigue and frustration associated with parenting, teaching, advocating, and interpreting for that child. Some also expressed fear of alienating professionals essential to the child's education if they demand additional or different programming.

In addition to their emotional responses, parents are confronted by the task of raising a child who is deaf or severely HOH in the absence of useful information about deafness. Yet, if they are to become effective advocates for their child and informed decision-makers in the child's educational program, they needed to understand the impact of deafness on family interactions and on the child's education and cognitive, social, and linguistic development. Parents were best informed about these issues by other parents of deaf or HOH children.

In fact, research indicated that parents need regular contact with other parents of deaf or HOH children who can lend emotional and social support and may have faced similar decision points in the lives of their child who is deaf or HOH. These support systems allow parents to express their feelings about their child's deafness, alert them to choices on their child's academic horizon, and provide the opportunity to discuss and evaluate information about deafness and the plethora of programs, assistive devices, and "cures" for deafness. Additionally, parent groups acknowledge the legitimacy of parents' emotions and affirm parental perogatives in making decisions for their deaf or severely HOH child.

Calderon and Greenberg (1993) suggest the following strategies for helping hearing parents successfully parent their deaf or HOH child: (a) assess family dynamics and coping styles including the marital relationship as well as parents' adjustment and roles within the family; (b) expand parents' personal mastery and control and strengthen their roles as models for their child by increasing their problem-solving skills; (c) develop strong support networks for parents to meet their social, emotional, and informational needs; (d) encourage home-school collaboration throughout the child's school career; and (e) provide a developmentally appropriate continuum of services. Additionally, regular interaction and conversation with adult deaf persons are critical for helping hearing parents of a young child who is deaf or severely HOH understand the visual world within which that child lives.

Learning

Although there is little empirical information about deaf children as thinkers and learners, hearing loss apparently alters their learning styles so that they often depend on experiential/visual learning modalities. Further, because these children have no undistorted access to the flow of language and information in the environment, they quite reasonably can demonstrate gaps in vocabulary, language, and conceptual knowledge, especially understanding and using abstract concepts. These recurring differences in the learning of a child who is deaf or HOH highlight the necessity of specifically teaching concept generalization and transfer through direct instruction, repetition, review, simplification, and clarification.

In her observations of the interactions between children and their mothers, Lederberg (1993) found that children who are deaf constantly shifted their attention between the task and their mothers. In contrast, hearing children remained visually focused on the task while listening to their mothers' oral input. She observed that mothers of children who are deaf intruded on learning by forcing them to pay attention even when they could more appropriately focus on the task. Three suggestions arise from Lederberg's research:

1. Encourage parents and teachers of a deaf or HOH child to assist him to divide his attention between the task and the adult without impeding learning.

2. Follow the child's lead in learning, attracting attention to oneself at appropriate points during an activity and waiting for the child's attention before communicating.

3. Recognize when the deaf child is communicating and help her capture the parent's and others' attention.

When parents and the school communicate routinely, a deaf or HOH child's learning is enhanced because regular home–school interactions help ensure consistency in signs, behavioral expectations, and academic goals. Parents are encouraged to observe their child's classroom to see other children who are deaf or HOH and ways their child fits within the group. The school also bridges the gap between parents and community resources by assisting parents in obtaining adaptive equipment and contacting service organizations such as the Lions Club.

Finally, it is important that the individual child who is deaf or HOH have access to the educational services that match his cognitive abilities and communication capabilities. Evaluating the appropriateness of a deaf or HOH child's program includes using CBA and other tools to identify precisely her skill levels. Then, interpreters, notetakers, and adaptive equipment such as captioners and TDDs allow the child to participate fully in the instructional environment. School buildings must also be conducive to learning through attention to lighting, acoustics, and space needs and provision of a safe environment with equipment such as lighted fire alarms.

Emotional and Social Development

The child who is deaf or severely HOH often exhibits significant emotional and social needs at school and home. This leads parents and teachers to express concern about teaching him to conform to social expectations in the absence of a reliable means of communication and to sometimes even question the child's competency (Lederberg, 1993). Teachers in an integrated setting often describe a child who is deaf or HOH as immature, lazy, stubborn, aggressive, inattentive, physical, a loner, inappropriate, unable to complete assignments, unable to keep up with the class, and unable to understand directions and directives. Parents report the following behaviors in their young child who is deaf or HOH: hitting, pinching, biting, temper tantrums, screaming, wanting it now, lack of awareness of danger, short fuses, problems with social group interactions, difficulty generalizing behavior from one situation to another, exaggerating, and depending on mother. Therefore, it is vital to include a deaf or HOH child's emotional needs and the appropriate expression of those needs on her IEP.

The behavior of a child who is deaf or HOH, rather than suggesting pathology, more often indicates that he does not immediately understand the behavioral expectations of hearing adults. When verbal skills are limited, her behavior may serve as a physical expression of emotion. Additionally, a child who is deaf or HOH may experience risk factors such as lack of a common language with parents and others in the hearing community; lack of a nonhearing peer group at home, school, and in the neighborhood; and lack of opportunity to interact regularly with members of the deaf community. Of particular relevance to the development of social skills and self-esteem of a child who is deaf or HOH is his limited opportunity to control the environment or to observe deaf adults functioning successfully in both the hearing and deaf communities. Finally, a deaf or HOH child who is not proficient in either sign or speech is at risk of social and academic failure. Any of these factors alone or in combination may compromise the deaf or HOH child's optimal social development.

Leigh and Stinson (1991) identified interactions with others as the primary means through which a deaf or HOH child's social skills and language develop and the source of personal understanding, self-efficacy, and self-esteem. They concluded that social development proceeds along two tracks: (a) a vertical track where the child is mentored by experienced members of the culture, such as parents, teachers, neighbors, and older children who model and teach cultural expectations for behavior, and (b) a horizontal track in which the child learns to negotiate interpersonal relationships and communicate with children her own age, including siblings and peers.

Social Skills

Deaf and hearing children differ in typical peer interactive patterns. Compared to a hearing peer, a child who is deaf or HOH uses less communication when playing, engages in less imaginative and cooperative play, and prefers to play with one or two children (Lederberg, 1993). A child who is deaf or severely HOH is different, not deficient, in social interactions. He derives similar benefits from social interactions that a hearing child enjoys, including immediate satisfaction of social needs and acquisition of social skills which will be important to him as an adult.

A child who is deaf or HOH needs peers of comparable age and language with whom to interact and communicate and the opportunity to find models through whom to learn appropriate social behaviors and develop self-identity (CED, 1988). This child rarely interacts with both hearing and deaf peers, choosing instead peers and models selectively on the basis of language usage. The deaf or HOH child competent in oral skills often interacts with hearing peers, while the child who is competent in sign usually interacts with deaf peers. Further, because a mainstreamed child who is deaf or severely HOH interacts primarily with other deaf or HOH children or teachers, the goal of socially integrating this child with hearing peers is rarely accomplished unless she receives supportive services (Leigh & Stinson, 1991; Mertens, 1989). Whether the child who is deaf or HOH interacts with hearing or with deaf peers, language and social development are enhanced. Thus, the goal of learning to interact with both deaf and hearing peers is not realized for most children who are deaf or severely HOH.

A child who is deaf or severely HOH needs to be comfortable not only with the persons with whom to interact, but also with the content of those interactions. This child often feels left out of social interactions because he doesn't understand jokes, the connotations of words or the idioms, cliches, colloquialisms, and other symbolic and shorthand ways that hearing individuals communicate. Moreover, the child who is deaf or HOH does not follow or participate in formal group discussions and informal kidding around. Much of what hearing children talk about in groups such as the lyrics to popular songs, the story line and vocabulary of television and movies, and slang expressions is outside the experience of the child who is deaf or HOH. She must be directly taught the latest age-appropriate jokes and the "cool" language used by hearing peers as well as strategies for following and understanding the gist of conversations.

For a child who is deaf or severely HOH to express emotions appropriately, it is important to teach him behaviors and emotional expressions that are not only socially appropriate in the hearing world but also effectively assert the child's rights without offending others. This is best accomplished when parents and teachers model positive expression of feelings and also teach the child who is deaf or HOH the appropriate sign and/or word with which to communicate an emotion. Moreover, the child needs experience in identifying options for behavior and the consequences of those various options and then permission to choose a behavior on the basis of that information.

The child who is deaf or HOH often lacks the social amenities of the hearing world and may alienate hearing persons by repeatedly touching them or speaking bluntly. She is often awkward in social aspects of communication including initiating and exiting conversations, giving compliments, saying no, making friends, and tailoring conversations for social circumstances or the needs of participants. This child needs to learn the social conventions of conversation through programs such as Skillstreaming and guided practice in the art of casual and formal communication.

Teaching social expectations to a child who is deaf or HOH includes clarifying rules and the circumstances in which they apply. Behavioral contracts for appropriate social behavior are negotiated with the child and the rewards and consequences of the behavior applied in a timely and equitable manner. Additionally, as a means of relieving the tension and frustration that arise from communicating and interacting socially with the hearing world, a child who is deaf or HOH needs to learn relaxation and stress reduction techniques such as deep breathing, counting to ten, and sequentially relaxing muscles.

As the adolescent child who is deaf or HOH experiences the teenager's typical need to belong, he may want to dress like his hearing peers and sometimes even grow his hair somewhat longer to cover the hearing aids. Further, he needs to acquire the visually oriented leisure and recreational skills such as card, board, computer, and arcade games which are the vehicles of social interaction among hearing adolescents. The child should also learn sports such as swimming, skiing, and biking that provide exercise, recreation, and opportunities for social interaction.

Finally, the successful acquisition of social skills by persons who are deaf or HOH who attended schools for the deaf sheds light on how to enhance the social skill acquisition of the child who is deaf or HOH in public education. The experience of these individuals indicates that exposure to multiple persons who are deaf or severely HOH can provide open access to communication with peers through the use of signs. Further, the observations by deaf adults and adolescents provide the basis of suggestions for eliminating feelings of isolation, loneliness, and lack of connection with hearing students (Mertens, 1989). According to adults who are deaf, the benefits of attending a school for the deaf that later translate into successful experience in the deaf community included the signing skills of teachers, convenient socialization with peers, and the opportunity to participate in extracurricular activities (Mertens, 1989). Thus, the experience of socially competent persons who are deaf underscores the necessity of providing each child who is deaf or severely HOH with access to formal and social opportunities to communicate with others and model interpersonal interactions.

Self-Awareness

Deafness has a serious impact on a deaf or HOH child's development of a positive self-esteem (Kessler-Grimes & Prichett, 1988). Moreover, it is through their reflection in the eyes of mothers and other significant others that both hearing and deaf or HOH children develop self-concepts. If the child senses that others perceive her as valuable, capable, and lovable, then she is more likely to develop a positive self-concept. However, despite the positive regard of their mothers, a child who is deaf or severely HOH may equate her differences from siblings and peers with inferiority (Kessler-Grimes & Prichett, 1988). In effect, the experiences of a child who is deaf or HOH may override a parent's expressions of love and support.

It is not uncommon for a child who is deaf or severely HOH to describe himself as unimportant and dumb and express self-consciousness about hearing aids and other visible signs of difference from hearing siblings and peers. To counteract feelings of worthlessness and isolation, a child who is deaf or HOH often prizes physical attractiveness, sports prowess, or other external attributes as indicators of personal value. To develop positive self-esteem, this child must learn about his worth and competence through positive experiences rather than relying on superficial indicators of value.

Self-understanding is the key to the deaf or HOH child's distinction of difference from deficiency. A child who is deaf or severely HOH often feels "stupid" because she sees hearing peers respond quickly to teacher directions. She does not understand that her slower processing time is related to the inability to hear oral instructions. The child who is deaf or HOH must be directly told about the implications of the hearing loss and that deafness comes from the ears not from limitations in the brain.

Strategies for teaching a child who is deaf or HOH about himself include telling him about personal strengths and needs and explaining which areas such as vocabulary, speech, reading comprehension, and math applications are especially affected by the deafness. It is necessary to go beyond simply providing the child with this information and ensure that he understands and owns this information. Finally, a child who is deaf or HOH needs to identify his own personal characteristics, especially strengths, and then call upon those strengths by engaging in recreational, social, and educational activities.

Additional strategies that enable a child who is deaf or severely HOH to perceive self-worth and develop positive self-esteem include assigning her real responsibilities that can be carried out successfully and then providing frequent and legitimate feedback about her efforts. For example, the child should be encouraged to act independently by engaging in such activities as making a purchase at a convenience store, finding an item in the grocery store, or ordering from the menu at a fast food restaurant. Feedback includes information about the child's success in completing the task as well as evaluation of the effort and attention the child applied to the accomplishment. Further, a child who is deaf or HOH should be asked for her opinions, preferences, feelings, and ideas and included regularly in conversations at home and school. These opportunities must also include visually adapting the situation to maximize the child's understanding. Finally, it is important for parents and teachers to remember that several people talking at once will quickly discourage a child who is deaf or HOH from participating in group interactions.

Communication

Communication is not language, although language is among the most important means used to communicate (Garretson, 1990; iii). Communication is the interaction between two or more persons and includes encoding and decoding thoughts and feelings through any medium that conveys a message. Speech is the mechanical act of producing oral language. There may be considerable discrepancy among the communication, language, and speech skills of the child who is deaf or severely HOH. For example, he may have clear and intelligible speech, but language, the content of the message, may be significantly below the child's chronological age. Whether at home or at school, focusing on the deaf or HOH child's speech and language production to the exclusion of social, academic, or interactive needs emphasizes an area of special difficulty for the child and communicates to him that his value is intimately tied to speech and language proficiency (Kessler-Grimes & Prichett, 1988).

Although signing is the natural language of persons who are deaf or severely HOH, this visual spatial language is not the natural language of most of their parents. Typically, a child who is deaf or HOH does not learn either signs or her parents' spoken language through natural exposure and imitation. Because she and her parents do not share a common language or communication system, she may not find the support and input which the family could provide (Rittenhouse, Jordan, Overton, Freeman, & Jaussi, 1991).

Parents of a child who is deaf or HOH expressed less concern about the mode of communication than the need to communicate with their child (Morgan-Redshaw, Wilgosh, & Bibby, 1989). Most found that their child adopted a means of communicating when parents resisted speaking for the child and allowed him to communicate on his own. Nevertheless, mothers and older siblings often act as interpreters for the child who is deaf or HOH, especially when listeners were unwilling to communicate directly with the child. Siblings expressed anger at the expectation that they not only must interpret for a deaf or HOH sibling, but also must account for and explain the behavior and needs of the child to others in the community.

American Sign Language

According to Newell (1990), American Sign Language (ASL) is a complete language system, including a variety of dialects that reflect regional, situational, personal, and interactive needs and styles. ASL is the fourth most commonly used language in the U.S. (Christensen, 1990). However, not all deaf individuals use ASL or one of its variants. Further, because few deaf children are born to deaf parents, ASL is rarely transmitted from parent to child but is often learned from interacting with peers at schools or other centrally based programs where there is a critical mass of students who are deaf or severely HOH.

Bragg (1990) cited several reasons why parents and teachers find learning, and by extension teaching, ASL difficult: (a) a defeatist attitude toward deafness, (b) fear of learning a new and different language, and (c) the awesome challenge of developing sufficient proficiency in ASL to communicate with and teach the child. Most parents and hearing teachers use a pidgin form of signed English that includes ASL vocabulary. Many lack proficiency in ASL, including dialectical variations, which restricts the deaf or HOH child's opportunity to learn this visual/spatial language system. Additionally, the attempts of these parent and teacher models to teach ASL in the artificial environment of the classroom and in the context of lessons further complicates its acquisition by the child who is deaf or severely HOH.

Proficiency in signing includes transmitting and receiving signs and fingerspelling proper words. However, Anderssen (1990) differentiated proficiency in signing from proficiency in communicating by stating that proficiency in communication meant that the person who is deaf or HOH understood what another said and also conveyed her emotions and ideas. In contrast, proficiency in signing is a technical skill that does not communicate if the signer is unwilling to convey a message because of a negative attitude. There are three basic requirements for a child who is deaf or severely HOH to develop communicative proficiency in ASL: (a) exposure to fluent users of ASL who sign regularly, (b) natural acquisition through communication rather than lessons in ASL, and (c) beginning learning of ASL during the preschool years (Cornett, 1990). Similar characteristics are relevant to the child who is deaf or HOH learning spoken English.

A child learns whatever language is modeled by significant others in his life. The deaf or HOH child who has limited exposure to adults proficient in ASL must rely on his hearing parents and teachers to model both sign language and spoken English. The success of this child's learning of either language depends, at least in part, on the language proficiency of the model.

Typically, the child who is deaf or HOH communicates during her formative years of language development with parents and teachers who are themselves just learning to sign. Parents who are beginning signers are awkward with signing and experience tremendous fatigue when communicating through this second language for them. Many are reasonably concerned that the signing skills of their deaf or HOH child will surpass their own. Parents' effort and commitment to signing to their child who is deaf or HOH need to be acknowledged and supported. Additionally, professionals who are competent signers should model signing for parents. Finally, parents should be taught stress management/relaxation techniques to relieve tension from trying to communicate with their child in an unfamiliar language.

For the child who is deaf or severely HOH to become fluent in sign as a means of communication and as an avenue to cognitive, social, and academic growth, he needs frequent opportunities to interact with fluent users of ASL. Regular interaction by the child and his parents with the deaf community helps shift part of the burden of the child's learning ASL to natural models of this language. Furthermore, contact with fluent users of ASL allows the child who is deaf or HOH to develop higher order thinking skills through modeling and participation in conversations (Nelson, Loncke, & Camarata, 1993).

Deaf Community

The deaf community is primarily an adult culture with identified members in schools or social organizations for the deaf. Like any culture, this community is not a monolith in which all members are the same; however, most members are proficient in ASL, abide by its rules and expectations for behavior and interactions, and share a common history and traditions. Facility in ASL is the cornerstone for acceptance and success in the deaf community and facility with ASL, as with any language, is the marker of social and cognitive competence.

Because of their difficulty communicating in spoken language, many persons who are deaf use spoken English as a vehicle for interacting with the hearing world. However, deaf educators and parents often emphasize the deaf or HOH child's reliance on residual hearing and communication skills, including listening and spoken language. The use of residual hearing and oral communication to the exclusion of ASL separates many persons who have a hearing loss from the deaf community, especially if the individual is thought to be trying to "pass" as hearing. A critical point to remember is that members of the deaf community frequently differ from parents and educators in judging who is socially and cognitively competent.

Recently, the deaf community affirmed its existence as a minority group. Like many minority groups, members of the deaf community rejected pressure to place themselves in the proverbial melting pot and merge with the dominant hearing society. Further, many in this group equate deaf education in the public schools with bilingual education and support the goal of teaching the child who is deaf or HOH to communicate in sign and spoken English. Therefore, although there is a preference for interaction with other members of the deaf community, most persons who are deaf recognize that bilingual education potentially expands their opportunities to interact with the hearing world.

The National Association of the Deaf's position statement on communication and language expresses the deaf community's goals for bilingual education for deaf children.

> Inherent in our Communication Position is our recognition of American Sign Language (ASL) as a language in its own right, fully deserving of respect because of its importance to deaf people for its communication, educational and cultural values. The NAD recognizes that two languages in the deaf community are ASL and English and that deaf individuals have the right to become fluent in both languages and the right to choose and utilize whichever language, communication approach, or combination of approaches that best meets their personal needs in varying situations.

Although most adolescents who are deaf or HOH explore the deaf community in their search for personal identity, this does not constitute rejection of the values of hearing parents. Parents' fears of losing their deaf or HOH child to the deaf community is minimized by routinely providing opportunities to interact with adolescents and adults in that community. Moreover, expecting the child who is deaf or HOH to choose between the hearing and deaf communities is an artificial choice in that optimally she is provided with the communication skills to flow back and forth between both groups.

In addition to having a language model, the child who is deaf or HOH needs consistent and regular exposure to deaf peers and adults because, without this contact, he shows limited social development (CED, 1988). This exposure is central to improving the emotional health and maturity of the deaf or HOH child who exhibits low self-esteem, withdrawal, or inappropriate behavior (CED, 1988). Lack of adult deaf role models results in the child drawing erroneous conclusions about the future such as believing that he will become hearing someday or will not survive into adulthood. In addition, he and his family need information about the deaf culture and deaf heritage, including access to deaf-focused magazines such as the *World Around You, Deaf America, and Deaf Life*. Further, the child who is deaf or HOH and her family should avail themselves of the opportunity of participating in activities and organizations for the deaf such as deaf olympics, the National Association of the Deaf (NAD), and junior NAD.

SUMMARY

This chapter is best summarized by a quote from Thomas (1989):

> There is another approach to deafness, which is a cultural, social definition. Instead of trying to cure it, and make people as hearing as possible, you accommodate it. This means that physiologically, psychologically, you start with the premise that a child is deaf and is going to stay deaf, and you embrace that premise. In other words, you allow the child to be who he or she is. (p. 25)

Best Practices in Planning Effective Instruction for Students Who Are Visually Impaired or Blind

Sharon Bradley-Johnson
Central Michigan University

OVERVIEW

Definitions

Few students classified as visually impaired are totally blind. Most are able to perceive light and see details to some extent. In the United States, more than 75% of persons who are blind have some usable vision (American Foundation for the Blind, undated).

The classification "legally blind" makes one eligible for government benefits. This classification applies when visual acuity is 20/200 or less in the better eye with correction or when there is restricted visual field with a diameter of no more than 20 degrees. The definition of legally blind is not helpful in educational planning because those students whose vision is 20/200 in the better eye often can use visual material in the classroom setting (Scholl, 1985). Hence, for clarity in this chapter, the term "blind" will be used to describe students who have to use senses other than vision for learning in the classroom setting.

Students who are blind will need tactile and auditory input for instruction. They will require specialized equipment and materials such as voice or Braille output computers, talking calculators, Braille material, recorded material, or raised line paper. For the purpose of determining eligibility for special education services, these students would be classified as visually impaired.

Other students classified as visually impaired who are not blind are those who need more than glasses in order to function well in the classroom. This group of students includes those described as having "low vision," who are able to see material that is held close to their eyes. Students classified as visually impaired may be able to read regular type or may require large-type materials. A number of these students use low vision equipment including magnifiers or closed circuit television (CCTV) where text is magnified electronically and shown on a television monitor. Even though these students have some vision that can be used for reading, some may require the use of tactile and auditory material for instruction.

Incidence

According to the U.S. Department of Education (1992), 17,783 students classified as visually impaired were served under the Individuals with Disabilities Education Act of 1990 (IDEA), Part B. These students comprised 0.4% of special education students between the ages of 6 and 21. During the 1989–90 school year, 84.1% of students classified as visually impaired attended regular schools, 4.5% attended a separate school, and 10.9% attended residential facilities. Students with multiple impairments were not included in these percentages.

Etiology

The group of students classified as visually impaired is very heterogeneous. There are many types and degrees of visual loss. Thus, there are numerous etiologies. Congenital losses can have genetic etiologies or result from prenatal damage. For school-age students, most visual losses are congenital (Scholl, 1985). The specific cause of a congenital loss, however, is frequently unknown (Finkelstein, 1989). Acquired visual losses can occur because of diseases or accidents.

The most frequent types of visual loss for school-age students are retrolental fibroplasia, congenital cataracts, optic nerve atrophy, and albinism (Hatfield, 1975).

Consultation with a student's medical specialist, teacher, and the consultant certified for working with students who have a visual loss should be helpful in understanding a particular student's condition. A multidisciplinary approach is essential in order to work effectively with these students.

Onset and Progression

Age at onset of the visual loss has implications for instruction. Children for whom the onset is after five years of age typically retain visual memories, such as memories for color and visual images. These memories can be used to facilitate acquisition of language concepts as well as other skills. For example, it is easier to instruct a child who remembers what a castle looks like than it is to have to teach such a concept to a child with little usable vision. Students unlikely to have visual memories may not have a satisfactory understanding of some concepts. Furthermore, some students who are visually impaired or blind may use concepts correctly but have learned the concepts only by rote. Hence, it is wise to probe questionable responses to ensure adequate understanding.

Whether the onset is gradual or sudden also has implications for instruction. When the loss is gradual, it is important to teach as much information as possible that requires vision while a student is still able to use visual input. Students who are experiencing a progressive loss may need support and counseling to help them adjust to their changing condition. Those students who experience a sudden loss of vision also are likely to require support and counseling, but this assistance would be to help them cope with this dramatic change in their lives. Those who experience a sudden loss of vision, leaving them with little usable vision, will need to adapt to the use of tactile and auditory input for instruction and, in many cases, to a new mode for written expression.

BASIC CONSIDERATIONS

Multidisciplinary by Necessity

In the large majority of cases, it is not possible to plan a comprehensive, effective instructional program for a student who is visually impaired or blind without using a multidisciplinary approach. When planning programs for these students, the three key disciplines with which a school psychologist must work are teachers certified in working with students who are visually impaired or blind, medical specialists, and orientation and mobility instructors.

A recent development in the education of students who are visually impaired or blind is the use of functional vision assessments. Such assessments are carried out by a teacher certified in working with these students, and the results have important implications for classroom instruction. Because such assessments are relatively new, they are not currently required in all states. Results from functional vision assessments describe how a particular student uses his or her vision when performing various academic and daily living tasks. In the school setting, these assessments are carried out with children from infancy through adolescence. The reports based on functional vision assessments contain recommendations regarding conditions, materials, and equipment needed for instruction for a particular student. For example, a report might provide information about appropriate lighting, viewing distance for materials, appropriate media for a student for reading and writing, size of type required, and recommendations for low-vision equipment.

Reviewing medical reports is critical to understanding a student's loss of vision. Ophthalmologists' and optometrists' reports will include a description of medical interventions needed, prescriptions, and any required restrictions on eye use.

Reading a medical report can be frustrating because of the terminology and the abbreviations encountered. Following is a list of common abbreviations and their meaning that may be useful when reading these reports.

- O.D. — ocular dexter (right eye)
- O.S. — ocular sinister (left eye)
- O.U. — oculi unitas (both eyes)
- W.N.L. — within normal limits
- S., S.S., S.C. — without correction
- C., C.C. — with correction
- N.L.P. — no light perception (totally blind)
- P.P. — near point
- P.R. — far point
- V.A. — visual acuity
- V.F. — visual field
- N.V. — near vision
- L.P. — light perception

Information in the medical report will describe visual acuity measured separately for each eye. Furthermore, visual acuity will be measured with and without correction, that is, with and without glasses. Typically such information is given for both near-vision and distance viewing.

Recommendations from a medical report may not apply to the classroom environment. Anxiety and the unfamiliar environment of a medical office may affect a student's use of vision. Thus, information from a functional vision assessment also is needed because this assessment is conducted within the school environment.

It is important that vision assessments are current — having been done within about a year — because visual conditions change resulting in changing needs for the student. Not only should vision assessments be current, but hearing reports must be up to date as well. Students who are visually impaired or blind rely so heavily on what they hear that it is important to ensure that hearing ability is maximized.

An orientation and mobility instructor has specialized training for teaching students who are visually impaired or blind how to travel about effectively and safely. When someone untrained in orientation and mobility observes a student who is visually impaired or blind travel about, he or she may think that the student does quite well considering the visual loss. An orientation and mobility specialist when making the same observation, however, may be able to suggest several things that could considerably increase a student's level of independent functioning. Hence, assessment and intervention by a specialist in this area is an important component of an educational program for a student who is visually impaired or blind. Training in orientation and mobility skills should begin as early as preschool. Examples of skills taught include appropriate gait and stride when walking and ways to travel safely and independently within both school and home environments and to seek help when assistance with orientation and mobility is needed.

Thus, to develop comprehensive, well coordinated educational programs that meet the needs of students who are visually impaired or blind, school psychologists must collaborate with other professionals, especially teachers certified in working with these students, medical specialists, and orientation and mobility specialists.

Family and Home Environments

Adjustment to having a child with a serious visual loss can be difficult, especially when family members have had little or no contact with persons who are visually impaired or blind. Family members are likely to go through the various stages of grieving when first informed of the condition. Parents may be very concerned, even frightened, about the prospect of raising a child who is visually impaired or blind. There are several things a school psychologist can do to assist the family in making the adjustment.

Besides providing support and counseling, the school psychologist can arrange for the family to talk with adults who are visually impaired or blind. These adults can share their experiences and discuss concerns the parents may have. The fact that most children who are visually impaired or blind grow up to be happy, productive adults needs to be emphasized. Also, arranging for family members to talk with other families who have children with serious visual losses can be helpful.

For families of infants, a family assessment must be conducted to determine the family's needs and interests with regard to their child. Such an assessment may be needed for preschoolers as well and can be of assistance to some families of older children also. For a comprehensive discussion of family assessment, see *Family Assessment in Early Intervention* (Bailey & Simeonsson, 1988).

A number of skills tend to be delayed for young children who are visually impaired or blind, though many of these delays can be lessened or eliminated with appropriate instruction. See Bradley-Johnson (1994) for a discussion of these areas. It is important for parents to be aware of these potential delays in development. Having this knowledge in advance may help parents cope when developmental milestones are not attained at the time they would be for sighted children. The component of family assessment that addresses such events is particularly important for families with children who are visually impaired or blind. Bailey et al. (1986) have developed a Critical Events Checklist to address concerns for families of infants and young children with disabilities.

Clearly it is important that parents are closely involved in educational planning for their child and that their interests and concerns are solicited and utilized in planning. Communication with parents will be enhanced during this planning process if professionals avoid the use of jargon.

BEST PRACTICES

Infants, Toddlers, and Preschoolers

There are several unique issues involved in planning instructional programs for infants who are visually impaired or blind. Some parents, especially those with little or no experience with others with a significant visual loss, may benefit from information regarding how to interact appropriately with their infant. Modeling appropriate interaction with their infant can be helpful.

Because infants who have little or no useful vision do not make eye contact or direct their gaze toward someone speaking to them, this can interfere with interactions. Parents may feel disappointed or even rejected in their attempts to interact with their infant and the frequency of their interaction may decrease because the baby is unable to make eye contact. Hence, these parents will benefit from learning to look for other behaviors indicating that their infant is responding to their attention. These behaviors can include any fairly consistent change in behavior following initiation of interaction by the parent. Examples include quieting, squirming, changes in facial expression, change in breathing rate, and increase in activity. Helping parents recognize these responses from their infant is important to enhance their relationship with the baby.

Young children learn a great deal through physical contact. This is especially true for children with a serious visual loss. Physical contact plays an important part in the development of social skills, language, cognition, and motor skills. If these children learn to find physical contact pleasurable, it will help to prevent the passivity and isolation that frequently characterize children with visual impairments. Thus, encouraging physical contact between the parents and infant or young child can be very beneficial. The use of infant sling carriers makes it easier for some parents to provide frequent physical contact. Their use also places the infant in an upright position making him or her more alert and providing a situation where the baby can experience varied stimulation.

It is important that parents consider how to initiate contact with their infant without producing a startle response from the baby. Because some infants with a visual loss are unable to see someone approach, contact should be made gradually (rather than suddenly), and it is helpful if the parent talks as he or she approaches.

Because children who are visually impaired or blind do not receive the visual input of sighted children, language development is slower for young children with a significant visual loss. Parents can help in this area by developing the habit of naming objects and describing their actions often, even for infants. For infants and young children up to the age of five years, the program *On the Way to Literacy* (Stratton & Wright, 1993) can be beneficial in terms of language development, parent–child interaction, and early book-handling skills. This program consists of a print handbook for parents or teachers and 10 tactile/visual storybooks to be read to children. The books are in Braille and print and include tactile and visual illustrations. For parents unsure of how to interact in ways helpful to their child who is visually impaired or blind, this program can provide a framework for interaction, while at the same time helping the parent teach useful language concepts and finger and hand skills.

Encouraging parents to use their child's name before saying something to the child is helpful for two reasons. Often these children are delayed in learning to respond to their names. Frequent use of the child's name provides practice in name recognition. Also, it lets the child know that what is about to be said is directed to her or him. Developing the habit of using the child's name first when speaking to an infant or young child is beneficial.

Safety is a primary concern for infants and young children, especially when there is impairment of vision or blindness. Interacting with the environment, however, is critical for these children in order to reduce passivity and enhance their learning. Often, in order to learn, these infants and children need more opportunities to explore the environment than a sighted child. Hence, a balance needs to be found between encouraging these children to explore their surroundings and ensuring their safety. Parents with children who are disabled often tend to be overprotective and thereby inhibit learning. Learning to avoid hazards and to respond appropriately to "no," are particularly important skills to teach these children. Consistency by parents will facilitate the acquisition of these skills, whereas inconsistency in responding to their child will interfere.

Unfortunately, social skills are delayed for many children who are visually impaired or blind. Often these infants and young children miss nonverbal cues such as gestures, facial expressions, and eye contact. Compared with sighted peers, they interact less, initiate fewer interactions, are less responsive and less reinforcing to others, and may display more negative affect (Preisler, 1988; Rogers & Puchalski, 1984; Skellenger, Hill, & Hill, 1992).

Clearly, social interaction is likely to require intervention to prevent delays and increase positive contact. To aid in goal setting and evaluation of program effects, the following measures should be of assistance:

- Systematic direct observation (such as interval or frequency recording).
- The General Social and Emotional Development section of the *Revised Brigance Diagnostic Inventory of Early Development* (Brigance, 1991), a criterion-referenced measure.
- The Self-Direction and Social Skills sections of *The Carolina Curriculum for Infants and Toddlers with Special Needs* (Johnson-Martin, Jens, Attermeier, & Hacker, 1991), a curriculum-based measure.
- The Socialization Skills section of the *Oregon Project for Visually Impaired and Blind Preschool Children* (Anderson, Boigon, & Davis, 1986), a curriculum-based measure.

These measures have either been designed for infants and young children with a visual loss or do not require vision.

Play skills are likely to require instruction as well. Parents can assist development in this area by providing appropriate toys. Toys that are large and make noise are easier for these infants and children to locate. Toys that are response contingent aid a child in learning that he or she is able to affect the environment, an important skill for a child with a physical or mental disability.

Parents should encourage an infant or young child who is passive to move and to explore the environment. Infants and children with little or no useful vision are not enticed by visual stimulation to explore their environment. Furthermore, because of extended stays in the hospital where they may have been restrained for medical reasons, some of these infants may be quite passive. These children will benefit from physical guidance to encourage them to move. It will be important to teach them to use their hands to turn and explore objects and also to search for objects that fall out of reach.

Measures for goal setting and monitoring progress of play skills include many items from measures listed for social skills as well as the Schemes for Objects scale from the *Ordinal Scales of Psychological Development* (Uzgiris & Hunt, 1989). The *Ordinal Scales* are appropriate for infants from birth to two years of age.

School-Age Students

A number of behaviors relevant to classroom functioning are important to consider when planning instruction for students who are visually impaired or blind. Because most of these students are likely to require more assistance than their sighted peers, they need to be able to request help, accept help, and refuse help appropriately. Classroom observation should indicate whether any of these behaviors should be targeted for instruction.

For efficient functioning in the classroom, they need organizational skills: keeping their desk well-organized, and routinely putting things away where they belong. These skills aid in avoiding frustration and unnecessary searches for materials. Such skills enable a student to function more independently.

Because of their reliance on auditory input, these students must have good listening skills. If attention and listening are problematic, instruction will be necessary and well worth the time required to remediate deficiencies.

Reading Braille takes about 2 1/2 times longer than reading regular type (Duckworth & Caton, 1986). Reading large type takes longer than regular type also. Furthermore, the use of limited vision is very tiring. Hence, additional time will be necessary for completing assignments and taking tests. Classroom performance and progress should be evaluated considering that fatigue is more of a factor for these students than for their sighted peers.

Goal setting and progress monitoring of classroom behavior can be done through the use of systematic direct observation. Also, the *Behavioral Rating Scale* (Swallow, Mangold, & Mangold, 1978), an informal checklist completed by teachers and designed specifically for students who are visually impaired or blind, can provide useful information on classroom behavior.

Because of potential delays, consideration of a student's social skills is an important part of instructional planning. The frequency and quality of interaction with peers should be examined. Participation in clubs, sporting events, and other after-school activities should be encouraged. Response to teasing may need to be addressed as well.

As noted earlier, social skills tend to be delayed for students who are visually impaired or blind. Several factors unique to students with a serious loss of vision may contribute to this delay. One of these factors has to do with their use of gestures and facial expressions. This type of nonverbal communication typically is learned from observation of others. Some students with a visual impairment are unable to observe such nonverbal communication. Hence, other people may find it somewhat difficult to interpret the emotions of these students because of their lack of typical gestures and facial expressions.

When speaking with someone, a sighted person turns his or her face toward the other person. Turning to this en face position is something that often must be taught to students with little or no useful vision. Orienting to a speaker may be difficult, especially when several people are speaking simultaneously. If a student has not learned to orient to a speaker or to the person to whom he or she is speaking, this should be targeted for instruction. If this skill is not taught, interactions with others could be unnecessarily awkward.

Though everyone engages in self-stimulation to some extent, students who are visually impaired or blind may self-stimulate at a higher frequency or by displaying some behaviors that make them appear unusual. These behaviors are most likely to occur when a student is bored or stressed. One type of self-stimulation seen in many of these children is eye pressing or poking. This behavior can begin around 12 months of age with frequent rubbing of the eyes, and by about 18 months can progress to a well-established habit of pressing the thumbs against the eyes (Scott, Jan, & Freeman, 1985). If allowed to continue, this can cause deeply depressed eyes discolored with dark circles which make a child look strange to others. Yet it can be a difficult habit to eliminate. Eye poking and body rocking are the most frequent forms of self-stimulation in young blind children and they tend to be quite stable behaviors (Brambring & Troster, 1992).

Of eye poking or rocking are observed, these behaviors should be targeted for remediation. Situations in which self-stimulation is likely to occur will need to be identified and programs developed to eliminate these behaviors. Ross and Koenig (1991) decreased head rocking in a child who was blind by use of a physical prompt. Brambring and Troster (1992) indicated that when these behaviors occur in children over 4 1/2 years of age they are particularly stable even if they are low frequency behaviors. Thus, intervention should begin as early as possible.

In addition to systematic direct observation, information from the *Social Skills Rating System* (SSRS; Gresham & Elliott, 1990) can be helpful in planning instruction in this area. The SSRS is completed by a teacher and each item is rated both for frequency of occurrence and for importance. This comprehensive system can be used with students from preschool through high school. No adaptations are required for students with a visual loss.

Well-researched programs for teaching social skills to school-age students include the *Social Skills Intervention Guide* (Elliott & Gresham, 1991), *The ACCEPTS Program: A Curriculum for Children's Effective Peer and Teacher Skills* (Walker et al., 1983), and *The ACCESS Program: Adolescent Curriculum for Communication and Effective Social Skills* (Walker, Todis, Holmes, & Horton, 1988).

Students who must read large-type material can be taught with regular basal readers where either the print is enlarged or magnifiers are employed. *Patterns* (Caton, Pester, & Bradley, 1980) is a basal reading program for teaching Braille reading and goes through a third-level reader. A systematic approach should be employed to teach Braille reading.

For goal setting and monitoring progress in reading, several useful options have been published. The *Braille Unit Recognition Battery* (Caton, Duckworth, & Rankin, 1985) is a criterion-referenced test for units of grade 2 literary Braille for students in grades 3 through 12. Examiners must be able to read Braille to use this test. The *Diagnostic Reading Scales* (Spache, 1981), are available in a Braille edition (Duckworth, 1992) or a large-type edition. This test provides information on a student's oral and silent reading levels (considering both decoding and comprehension), errors made in oral reading, and behaviors used when reading. Levels for the tests are mid-first to mid-seventh grade. Examiners do not need to be able to read Braille to use this test. For the *Comprehensive Diagnostic Inventory of Basic Skills* (Brigance, 1983), the *APH Tactile Supplement* (Duckworth & Abbot, undated) to this test can be used with Braille readers to obtain criterion-referenced information on a student's knowledge of phonics, structural analysis, and functional words. Finally, for monitoring progress in Braille reading, curriculum-based measurement (CBM) procedures seem to work well. If examiners have a regular-type copy of the material to be read, they do not have to be able to read Braille to use CBM with Braille readers.

In a study with elementary-age Braille readers, Morgan and Bradley-Johnson (in press) found that using the mean of three 2-minute samples of reading correlated better with results from a Braille transcription of the *Diagnostic Reading Scales* (Spache, 1981; r = .70 for decoding and .88 for comprehension) than the three 1-minute samples typically used with sighted students. This is not surprising, given that Braille takes about 2 1/2 times as long to read as regular type (Duckworth & Caton, 1986). Use of a 3-minute sample did not enhance the correlation. Test-retest reliability for the mean of the three 2-minute reading samples over a 2-week interval was .98. Hence, this appears to be both a reliable and valid measure of Braille reading performance. For more information on curriculum-based measurement, see Shinn (1989).

When planning instruction in the area of mathematics for young children who are visually impaired or blind, educators will need to use real objects. Because language concepts tend to be delayed for these children and some concepts may be learned only by rote, it is important to ensure that an adequate understanding of math concepts is acquired. Use of the quantitative and shape concepts sections of the *Revised Diagnostic Inventory of Early Development* (Brigance, 1991) can help in goal setting and progress monitoring for children up to the age of about 7 years. For children with little or no vision, the *APH Tactile Supplement* (Duckworth & Stratton, 1992) also will be needed. These two measures can provide criterion-referenced information on numeral comprehension, reading of Braille numbers, and understanding of ordinal position. For children having difficulty with addition, checking for understanding of the steps for meaningful counting (Englemann, 1969) using real objects is important because these skills form the basis for beginning addition. The four steps are:

> a) count 10 objects that are placed in a row, starting at either end, and answer the question "How many are there";
>
> b) count to a given number, and count out a specified number of objects from a group of ten objects;
>
> c) indicate the number that comes after any number in the 1–10 series;
>
> d) predict the number of objects what will be in a group if one is added. (Englemann, 1969, p. 253)

In order to demonstrate these skills, a child must be able to rote count and synchronize touch-and-count.

To determine skills learned and those to be taught next in arithmetic and mathematics for older students, the *Diagnostic Comprehensive Inventory of Basic Skills* (Brigance, 1983), in conjunction with the *APH Tactile Supplement* (Duckworth & Abbott, undated) for this scale, can be used with Braille readers. Skills measured include math facts, operations, fractions, decimals, time, measurement, mathematics vocabulary, and money.

For carrying out arithmetic operations, some students who are visually impaired or blind may use an abacus. Use of the abacus would be comparable to sighted students using scratch paper to work out their problems.

Unfortunately, no studies have been published on the use of curriculum-based measurement for mathematics for Braille or large-type readers.

With regard to written expression, students who have lost their vision after having learned to write may be able to use script writing on raised-line paper. This paper, available from the American Printing House for the Blind (see address in bibliography), may be helpful to other students who are visually impaired as well. For students who cannot use script writing, however, another method will be needed. Some students may use a brailler (similar to a typewriter, but for Braille) or the more portable slate and stylus. Writing in Braille is very time consuming. Others may use a computer system with speech output, print, or Braille. The *Informal Assessment of Developmental Skills* (Swallow, Mangold, & Mangold, 1978) contains informal checklists developed by teachers of students who were visually impaired or blind to assess skills in Braille writing, script writing, and typing.

To set goals and monitor progress in other written language skills, the ***Diagnostic Comprehensive Inventory of Basic Skills*** (Brigance, 1983) along with the ***APH Tactile Supplement*** for Braille readers (Duckworth & Abbot, undated) can be given to obtain information on capitalization, punctuation, spelling, writing sentences, addressing envelopes, and writing letters.

If an assessment of cognitive development is required for eligibility purposes, *Psychoeducational Assessment of Students Who Are Visually Impaired or Blind: Infancy Through High School* (Bradley-Johnson, 1994) contains detailed information regarding special issues to consider, a description of appropriate procedures, and a review of relevant measures.

SUMMARY

Planning instruction for infants, children, and adolescents who are visually impaired or blind is a time-consuming process when done well. There are a number of unique issues that require consideration. Coordinated efforts by a multidisciplinary team, including parents of the child or adolescent, the teacher certified in working with these students, medical specialists, an orientation and mobility instructor, and the school psychologist can be helpful to students. Fortunately, there are a number of useful new materials for instruction as well as new measures and procedures to help in setting goals and monitoring progress. Further research on the use of curriculum-based measurement for Braille and large-type readers would be helpful in the areas of reading, mathematics, and written expression.

ANNOTATED BIBLIOGRAPHY

American Printing House for the Blind (APH). P.O. Box 6085, Louisville, KY 40206. (1-800-223-1839.)

APH has the latest in educational materials and assessment instruments. APH publishes adapted and transcribed materials in Braille or large type as well as recorded books and magazines. The Printing House is a national nonprofit organization that publishes materials solely for persons who are visually impaired or blind.

Blind Children's Center, 4120 Marathon Street, Los Angeles, CA 90029. (1-800-222-3566).

The Center publishes a number of helpful booklets for parents of infants and preschoolers who are visually impaired or blind. Some topics include play, language, and movement. Copies are free to parents and inexpensive for professionals. Most booklets are available in English or Spanish.

Bradley-Johnson, S. (1994). *Psychoeducational assessment of students who are visually impaired or blind: Infancy through high school* (2nd ed.). Austin, TX: PRO-ED.

This undated edition emphasizes information useful for planning instruction. Extensive checklists are included for organizing assessment information. Also, checklists of procedures for each phase of assessment are presented along with detailed reviews of tests for social skills, play, language, cognition, achievement, and adaptive behavior.

National Federation of the Blind. (undated). *The blind child in the regular preschool program.* Baltimore: Author.

This fact sheet presents useful recommendations for helping regular classroom teachers understand the needs of these children. The fact sheet is free from the National Federation of the Blind, 1800 Johnson Street, Baltimore, MD 21230. (310) 659-9314.

Stratton, J. M., & Wright, S. (1993). *On the way to literacy: Early experiences for visually impaired children.* Louisville, KY: American Printing House for the Blind.

This program enables sighted parents, or parents who are visually impaired or blind, to read to and with their children who are visually impaired or blind. It is designed for children from infancy to age five. The handbook contains suggestions on how to use the program. The 10 storybooks have both tactile and visual illustrations as well as Braille and print text.

Appendix **I**

Principles for Professional Ethics

I. INTRODUCTION

The formal principles that guide the conduct of a professional school psychologist are known as *Ethics*. By virtue of joining the Association, each NASP member has agreed to act in a manner that shows respect for human dignity and assures a high quality of professional service. Although ethical behavior is an individual responsibility, it is in the interest of an association to adopt and enforce a code of ethics. If done properly, members will be guided towards appropriate behavior, and public confidence in the professional will be enhanced. Additionally, a code of ethics should provide due process procedures to protect members from potential abuse of the code. These *Principles* have been written to accomplish these goals.

The principles in this manual are based on the assumptions that: (1) school psychologists will act as advocates for their students/clients, and (2) at the very least, school psychologists will do no harm. These necessitate that school psychologists "speak up" for the needs and rights of their students/clients at times when it may be difficult to do so. School psychologists are also restrained to provide only those services for which they have acquired an acknowledged level of experience, training, and competency. Beyond these basic premises, judgment is required to apply the ethical principles to the fluid and expanding interactions between school and community.

There are many different sources of advice for the proper way to behave; local policies, state laws, federal laws, credentialing standards, professional association position statements, and books that recommend "Best Practices" are just a few. Given one's employment situation and the array of recommendations, events may develop in which the proper course of action is unclear.

As a general rule, the Association will seek to enforce the *Ethical Principles* upon members. The NASP *Standards for the Provision of School Psychological Services* are typically not enforced, although all members are encouraged to work towards achieving the hallmarks of quality services delivery that are described therein. Similarly, "position statements" and "best practices" documents are not adjudicated. In other words, one may consider the guidance of *Ethical Principles* to be more general, yet more enduring than other documents that reflect short-term opinions about specific actions that are shaped by local events, popular trends, or recent developments in the field.

The principles in this manual are organized into several sections as a result of editorial judgment. Therefore, principles discussed in one section may also apply to other sections. Every school psychologist, regardless of position (e.g., practitioner, researcher, university trainer, supervisor, state or federal consultant, administrator of psychological services) or setting (e.g., public or private school, community agency, hospital, university, private practice) should examine the theme reflected in each ethical principle to determine the application to her/his individual situation. For example, although a given principle may specifically discuss responsibilities towards "clients," the intent is that the standard would also apply to supervisees, trainees, and research participants. To obtain additional assistance in applying these principles to your particular setting, consult with experienced school psychologists, and seek advice from the National Association of School Psychologists or your state school psychology association.

II. PROFESSIONAL COMPETENCY

A. General

1. School psychologists recognize the strengths and limitations of their training and experience, engaging only in practices for which they are competent. They must continually seek additional training with the welfare of children, families, the school community, and their trainees or supervisees in mind.

2. Competence levels, education, training, and experience are accurately represented to clients in a professional manner.

3. School psychologists do not use affiliations with persons, associations, or institutions to imply a level of professional competence which exceeds that which has actually been achieved.

1096

4. School psychologists are aware of their limitations and enlist the assistance of other specialists in supervisory, consultative, or referral roles as appropriate in providing services.

5. School psychologists engage in continuing professional development. They remain current regarding developments in research, training, and professional practices that benefit children, families, and schools.

6. School psychologists refrain from any activity in which their personal problems or conflicts may interfere with professional effectiveness. Competent assistance is sought to alleviate conflicts in professional relationships.

III. PROFESSIONAL RELATIONSHIPS AND RESPONSIBILITIES

A. General

1. School psychologists are committed to the application of their professional expertise for the purpose of promoting improvement in the quality of life for students, their families, and the school community. This objective is pursued in ways that protect the dignity and rights of those involved. School psychologists accept responsibility for the appropriateness of their treatments and professional practices.

2. School psychologists respect all persons and are sensitive to physical, mental, emotional, political, economic, social, cultural, ethnic, racial, gender, sexual preference, and religious characteristics.

3. School psychologists are responsible for the direction and nature of their personal loyalties or objectives. When these commitments may influence a professional relationship, the school psychologist informs all concerned persons of relevant issues in advance.

4. School psychologists in all settings maintain professional relationships with students, parents, the school, and community. Consequently, parents and students are to be fully informed about all relevant aspects of school psychological services in advance. The explanation should take into account language and cultural differences, cognitive capabilities, development level, and age so that the explanation may be understood by the student, parent, or guardian.

5. School psychologists shall attempt to resolve situations in which there are divided or conflicting interests in a manner which is mutually beneficial and protects the rights of all parties involved.

6. School psychologists do not exploit clients through professional relationships nor condone these actions in their colleagues. Students, clients, employees, colleagues, and research participants will not be exposed to deliberate comments, gestures, or physical contacts of a sexual nature. School psychologists do not engage in sexual relationships with students, supervisees, trainees, or past or present clients.

7. School psychologists attempt to resolve suspected detrimental or unethical practices on an informal level. If informal efforts are not productive, the appropriate professional organization is contacted for assistance, and procedures established for questioning ethical practice are followed.

a. The filing of an ethical complaint is a serious matter. It is intended to improve the behavior of a colleague that is harmful to the profession and/or the public.

b. School psychologists enter into this process thoughtfully and with concern for the well-being of all parties involved. They do not file or encourage the filing of an ethics complaint that is frivolous or motivated by revenge.

8. School psychologists respect the confidentiality of information obtained during their professional work. Information is revealed only with the informed consent of the client, or the client's parent or legal guardian, except in those situations in which failure to release information would result in clear danger to the client or others.

9. School psychologists discuss confidential information only for professional purposes and only with persons who have a legitimate need to know.

10. School psychologists inform their clients of the limits of confidentiality.

B. Students

1. School psychologists understand the intimate nature of consultation, assessment, and direct service. They engage only in professional practices which maintain the dignity and integrity of students and other clients.

2. School psychologists explain important aspects of their professional relationships with students and clients in a clear, understandable manner. The explanation includes the reason why services were requested, who will receive information about the services provided, and the possible outcomes.

3. School psychologists understand their obligation to respect the rights of a student or client to initiate, participate in, or discontinue services voluntarily.

4. Recommendations for program changes or additional service will be discussed, including any alternatives which may be available.

C. Parents, Legal Guardians, and Appointed Surrogates

1. School psychologists explain all services to parents in a clear, understandable manner. They strive to propose a set of options which takes into account the values and capabilities of each parent.

2. School psychologists recognize the importance of parental support and seek to obtain this by assuring that there is direct parent contact prior to seeing the student/client. They secure continuing parental involvement by a frank and prompt reporting to the parent of findings and progress that conforms to the limits of previously determined confidentiality.

3. School psychologists respect the wishes of parents who object to school psychological services and attempt to guide parents to alternative community resources.

4. School psychologists discuss recommendations and plans for assisting the student/client with the parent. The discussion includes alternatives associated with each set of plans, showing respect for the ethnic/cultural values of the family. The parents are advised as to sources of help available at school and in the community.

5. School psychologists discuss the rights of parents and students regarding creation, modification, storage, and disposal of confidential materials that will result from the provision of school psychological services.

D. Service Delivery

1. School psychologists are knowledgeable of the organization, philosophy, goals, objectives, and methodologies of the setting in which they are employed.

2. School psychologists recognize that an understanding of the goals, processes, and legal requirements of their particular workplace is essential for effective functioning within that setting.

3. School psychologists attempt to become integral members of the client systems to which they are assigned. They establish clear roles for themselves within that system and the local community.

4. School psychologists who provide services to several different groups may encounter situations when loyalties are conflicted. As much as possible, the stance of the school psychologist is made known in advance to all parties to prevent misunderstandings.

5. School psychologists promote changes in their employing agencies that will benefit their clients.

E. Community

1. School psychologists are also citizens, thereby accepting the same responsibilities and duties as any member of society. They are free to pursue individual interests, except to the degree that these compromise professional responsibilities.

2. School psychologists may act as individual citizens to bring about social change in a lawful manner. Individual actions should not be presented as, nor suggestive of representing the field of school psychology.

3. As employees or employers, in public or private domains, school psychologists do not engage in or condone practices that discriminate against clients based on race, handicap, age, gender, sexual preference, religion, national origin, economic status, or native language.

4. School psychologists avoid any action that could violate or diminish the civil and legal rights of clients.

5. School psychologists adhere to federal, state, and local laws and ordinances governing their practice. If regulations conflict with ethical guidelines, school psychologists seek to resolve such conflict through positive, respected, and legal channels.

F. Related Professions

1. To best meet the needs of students and clients, school psychologists cooperate with other professional disciplines in relationships based on mutual respect.

2. School psychologists recognize the competence of other professionals. They encourage and support the use of all resources to best serve the interests of students and clients.

3. School psychologists strive to explain their field and their professional competencies, including roles, assignments, and working relationships to other professionals.

4. School psychologists cooperate with other professionals and agencies with the rights and needs of their client in mind. If a client is receiving similar services from another professional, school psychologists promote coordination of services.

5. The student or client is referred to another professional for services when a condition is identified which is outside the professional competencies or scope of the school psychologist.

6. When transferring the intervention responsibility for a student or client to another professional, school psychologists ensure that all relevant and appropriate individuals, including the student/client

BEST COPY AVAILABLE

when appropriate, are notified of the change and reasons for the change.

7. When school psychologists suspect the existence of detrimental or unethical practices, the appropriate professional organization is contacted for assistance in determining the procedures established by that profession for examining the practices in question.

G. Other School Psychologists

1. School psychologists who employ, supervise, or train other professionals accept the obligation to provide continuing professional development. They also provide appropriate working conditions, fair and timely evaluation, and constructive consultation.

2. School psychologists who supervise interns are responsible for all professional practices of the supervisees. They assure the students/clients and the profession that the intern is adequately supervised.

IV. PROFESSIONAL PRACTICES PUBLIC AND PRIVATE SETTINGS

A. Advocacy

1. School psychologists consider the students or clients to be their primary responsibility, acting as advocates of their rights and welfare. When choosing a course of action, school psychologists take into account the rights of each individual involved and the duties of the school personnel.

2. School psychologists' concerns for protecting the rights and welfare of students is communicated to the school administration and staff, and is the top priority in determining services.

B. Assessment and Intervention

1. School psychologists will maintain the highest standard for educational and psychological assessment.

a. In conducting psychological, educational, or behavioral evaluation, or in providing therapy, counseling, or consultation services, due consideration will be given to individual integrity and individual differences.

b. School psychologists respect differences in age, gender, socioeconomic, cultural, and ethnic backgrounds. They select and use appropriate assessment or treatment procedures, techniques, and strategies.

2. School psychologists collect relevant data using valued and reliable instruments and techniques that are applicable and appropriate for the benefit of the student or client.

3. School psychologists combine observations, background information, and information from other disciplines in order to reach comprehensive conclusions.

4. School psychologists use assessment techniques, counseling and therapy procedures, consultation techniques, and other direct service methods that the profession considers to be responsible, research-based practice.

5. School psychologists do not condone the use of psychological or educational assessment techniques by unqualified persons in any way, including teaching, sponsorship, or supervision.

6. School psychologists develop interventions which are appropriate to the presenting problems and are consistent with data collected. They modify or terminate the treatment plan when the data indicate the plan is not achieving the desired goals.

C. Use of Materials and Technology

1. School psychologists maintain test security, preventing the release of underlying principles and specific content that would undermine the use of the device.

2. School psychologists uphold copyright laws. Permission is obtained from authors to reproduce non-copyrighted published instruments.

3. School psychologists will obtain written prior consent or else remove identifying data presented in public lectures or publications.

4. When producing materials for consultation, treatment, teaching, public lectures, or publication, school psychologists acknowledge sources and assign credit to those whose ideas are reflected in the product. Recognition is given in proportion to the contribution. Plagiarism of ideas or product is a violation of professional ethics.

5. School psychologists do not promote or encourage inappropriate use of computer-generated test analysis or reports. For example, a school psychologist would not offer an unedited computer report as one's own writing, nor use a computer scoring system for tests in which one has no training.

6. School psychologists maintain full responsibility for any technological services used. All ethical and legal principles regarding confidentiality, privacy, and responsibility for decisions apply to the school psychologist and cannot be transferred to equipment, software companies, or data processing departments.

7. Technological devices should be used to improve the quality of client services. School psychologists will resist applications of technology that ultimately reduce the quality of service.

D. Research and Evaluation

1. In performing research, school psychologists accept responsibility for selection of topics, research methodology, subject selection, data gathering, analysis, and reporting.

2. In publishing reports of their research, school psychologists provide discussion of limitations of their data and acknowledge existence of disconfirming data, as well as alternate hypotheses and explanations of their findings.

E. Reporting Data and Conference Results

1. School psychologists ascertain that student or client information reaches only authorized persons.

   a. The information is adequately interpreted so that the recipient can better help the student or client.

   b. The school psychologist assists agency recipients to establish procedures to properly safeguard the confidential material.

2. School psychologists communicate findings and recommendations in language readily understood by the intended recipient. These communications describe potential consequences associated with the proposals.

3. School psychologists prepare written reports in such form and style that the recipient of the report will be able to assist the student or client. Reports should emphasize recommendations and interpretations; reports which present only test scores or brief narratives describing a test are seldom useful. Reports should include an appraisal of the degree of confidence which could be assigned to the information.

4. School psychologists review all of their written documents for accuracy, signing them only when correct.

5. School psychologists comply with all laws, regulations and policies pertaining to the adequate storage and disposal of records to maintain appropriate confidentiality of information.

V. PROFESSIONAL PRACTICES — PRIVATE SETTING

A. Relationship with School Districts

1. Some school psychologists are employed in both the public and private sectors, and in so doing, may create a conflict of interest. School psychologists operating in both sectors recognize the importance of ethical standards, the separation of roles, and take full responsibility for protecting and completely informing the consumer of all potential concerns.

2. A school psychologist, while working in the private sector, may not accept any form of remuneration from clients who are entitled to the same service provided by the same school psychologist while working in the public sector.

3. School psychologists in private practice have an obligation to inform parents of any free school psychological services available from the public or private schools prior to delivering such services for remuneration.

4. School psychologists working in both public and private sectors will conduct all private practice outside of the hours of contracted public employment.

5. School psychologists engaged in private practice do not use tests, materials, equipment, facilities, secretarial assistance, or other services belonging to the public sector employer, unless approved in advance through a written agreement.

B. Service Delivery

1. School psychologists conclude a financial agreement in advance of service delivery.

   a. School psychologists ensure to the best of their ability that the client clearly understands the agreement.

   b. School psychologists neither give nor receive any remuneration for referring clients for professional services.

2. School psychologists in private practice adhere to the conditions of a contract until service thereunder has been performed, the contract has been terminated by mutual consent, or the contract has otherwise been legally terminated.

3. School psychologists in private practice prevent misunderstandings resulting from their recommendations, advice, or information. Most often, direct consultation between the school psychologist in private practice and the school psychologist responsible for the student in the public sector will resolve minor differences of opinion without necessarily confusing the parents, yet keep the best interests of the student or client in mind.

4. Personal diagnosis and therapy are not given by means of public [illegible], newspaper columns, magazine articles, radio and television programs, or mail. Any information shared through mass media activities is general in nature and is openly declared to be so.

C. Announcements/Advertising

1. Appropriate announcement of services, advertising, and public media statements may be necessary for school psychologists in private practice. Accurate representations of training, experience, services provided, and affiliation are done in a restrained manner. Public statements must be made on sound and accepted theory, research, and practice.

2. Listings in telephone directories are limited to the following: name/names, highest relevant degree, state certification status, national certification status, address, telephone number, brief identification of major areas of practice, office hours, appropriate fee information, foreign languages spoken, policy regarding third party payments, and license number.

3. Announcements of services by school psychologists in private practice are made in a formal, professional manner, using the guidelines of section 2, above. Clear statements of purposes with unequivocal descriptions of the experiences to be provided are given. Education, training, and experience of all staff members are appropriately specified.

4. School psychologists in private practice may use brochures in the announcement of services. The brochures may be sent to professional persons, schools, business firms, government agencies, and other similar organizations.

5. Announcements and advertisements of the availability of publications, products, and services for sale are professional and factual.

6. School psychologists in private practice do not directly solicit clients for individual diagnosis or therapy.

7. School psychologists do not compensate in any manner a representative of the press, radio, or television in return for personal professional publicity in a news item.

PROCEDURAL GUIDELINES FOR THE ADJUDICATION OF ETHICAL COMPLAINTS

Section I. Responsibility and Function

The Ethical and Professional Standards Committee shall be responsible for developing and maintaining a clearly defined position for the Association regarding the ethical and professional conduct principles to be adhered to by its members and also the members of the National School Psychology Certification System (NSPCS). The major area of particular ethical concern to the Committee will be that of the protection and general well-being of individuals served by school psychologists, in schools and in private practice, and in institutions or agencies through which the service is rendered. The Committee is further charged to study and make recommendations to the Executive Board when it is alleged that a NASP or NSPCS member has failed to follow the ethical principles of the Association.

Members of the Ethical and Professional Standards Committee recognize that their role is an extremely important one, involving the rights of many individuals, the reputation of the profession, and the careers of individual professionals. They bear a heavy responsibility because their recommendations may alter the lives of others. Therefore, they must be alert to personal, social, organizational, financial, or political situations or pressures that might lead to misuse of their influence. The Ethical and Professional Standards Committee shall assure the responsible use of all information obtained in the course of an inquiry or investigation. The objective with regard to the individual shall, whenever possible, be constructive, rather than punitive in character.

The function of the Committee in investigating complaints of alleged ethical misconduct involves obtaining a thorough and impartial account of the behaviors or incidents in order to be able to evaluate the character of the behaviors in question. When responding to complaints, members of the Ethics and Professional Standards Committee have the responsibility to consider the competency of the complainant, to act in an unbiased manner, to work expeditiously and to safeguard the confidentiality of the Committee's activities. Committee members and their designees have the added responsibility to follow procedures which safeguard the rights of all individuals involved in the complaint process.

Section II. Scope and Authority

The Ethical and Professional Standards Committee shall address issues of ethical misconduct in an investigatory, advisory, educative, and/or remedial role. What constitutes ethical misconduct shall be determined on the basis of the provisions of the NASP *Principles for Professional Ethics* and any published advisory opinions that from time to time are developed by the Ethical and Professional Standards Committee. In applying the Principles, the authorized opinions of those charged by NASP with the administration and interpretation of the ethical principles shall be binding on all NASP members, individuals who hold a certificate issued by the National School Psychology Certification Board (NSPCB), and on the members of state associations affiliated with NASP.

When investigating and/or responding to a complaint or inquiry, the Ethical and Professional Standards Committee shall conduct itself in a manner consistent with the Bylaws of the Association and with the NASP *Principles for Professional Ethics* and shall also be bound by these procedures. The Ethical and Professional Standards Committee shall endeavor to settle cases informally, recommend disciplinary action when unethical conduct has occurred, report regularly to the Delegate Assembly on its activities and shall revise and amend (subject to ratification by the Delegate Assembly) the NASP Principles and these procedures in a timely manner. The Association may, at the recommendation of the Ethical and Professional Standards Committee, and in accordance with the Bylaws of the Association, expel a NASP member. The Ethical and Professional Standards Committee will also issue a recommendation to the NSPCB regarding charges filed against any nationally certified school psychologist.

When a complaint is received about a non-member, the Ethical and Professional Standards Committee shall respond only if the individual complained against is a member of the National School Psychology Certification System. Otherwise, the committee may act only in an advisory or educative fashion and shall have no authority to investigate the case or to discipline the individual in question.

Complaints that address concerns about professional standards, organizations, employers, and the like, shall be referred to the Ethical and Professional Standards Committee. Nevertheless, it should be recognized that in situations where an individual psychologist is being coerced to behave unethically, he/she bears certain ethical responsibilities and to fail to take appropriate action, e.g., refusing to behave ethically, could eventuate in charges of misconduct against the individual psychologist involved. However, as a rule, such "standards" concerns would not fall under the purview of this complaint process.

Complaints received by the Ethical and Professional Standards Committee shall be reviewed and judged on the basis of the *Principles for Professional Ethics* in force at the time of the alleged misconduct. Investigation and adjudication of ethical complaints shall be on the basis of the "Procedural Guidelines for the Adjudication of Ethical Complaints" in force at the time the complaint is received by the Committee.

Section III. Receipt and Acknowledgment of Complaints and Inquiries

A. The Ethical and Professional Standards Committee shall recognize and respond to all complaints and inquiries from any responsible individual or group of individuals in accordance with these procedures. The individual who petitions the Committee (hereinafter referred to as the *complainant)* need not be a member of NASP or the affiliated state association. Anonymous letters and phone calls will not be recognized. Complaints by members which are judged by the committee to be frivolous or revengeful may be cause for action against the complainant.

B. An oral complaint or inquiry may be informally handled, referred elsewhere when appropriate, or an Ethical and Professional Standards Committee chairperson may request that the complaint be formally submitted in writing. Only written statements expressing the details of the alleged misconduct will be accepted for action. Such written statements shall be signed by the complainant and should state, in as much detail as practicable, the facts upon which the complaint is based. All the correspondence, records, and activities of the Ethical and Professional Standards Committee shall remain confidential.

C. Within 15 days of receipt of a written statement outlining the details of the alleged misconduct, the chairpersons of the Ethical and Professional Standards Committee shall do the following:

1. Determine if the individual against whom the complaint is made (hereinafter referred to as the *respondent),* is a member of NASP or NCSP. If the respondent is not a member of NASP or NCSP, the complainant shall be so advised and when appropriate, referred to other agencies and/or associations who would have authority in the matter.

2. If the respondent is a member of NASP or NCSP, the Ethical and Professional Standards Committee chairpersons, with any advisory opinions deemed necessary, shall review the complaint. If it is determined that the alleged misconduct, even if true, would *not* constitute an actual violation of the NASP Principles, a chairperson shall notify the complainant.

3. If the information obtained from the complainant is insufficient to make a determination regarding the alleged misconduct, the chairpersons may send a written request to the complainant, asking for clarification and/or additional information as would be needed to make such a determination.

4. If it is determined that the alleged misconduct, if substantiated, would constitute an actual violation of NASP Principles, the Ethical and Professional Standards Committee chairpersons shall direct a letter to and advise the complainant that the allegation will be investigated by the Committee. The complainant shall be asked to sign a release, authorizing that his/her name be revealed to the respondent.

5. If the complainant refuses to permit his/her identity to be made known to the respondent, such refusal will serve as a basis for forfeiting the complaint process. However, the Ethical and Professional Standards Committee may proceed on its own volition when a member appears to have engaged in ethical misconduct that tends to injure the Association or to adversely affect its reputation, or that is clearly inconsistent with or destructive of the goals and objectives of the Association.

Section IV: Conduct of an Informal Inquiry

A. Within 15 days of receipt of the signed release, the Ethical and Professional Standards Committee shall inform the respondent, in writing, with the envelope marked "confidential," that a complaint has been filed against him/her. This letter shall describe the nature of the complaint, indicate the principle(s) which appear to have been violated, and request the respondent's cooperation in obtaining a full picture of the circumstances which led to the allegations. A copy of the NASP *Principles for Professional Ethics*, these procedures, and any pertinent advisory opinions of the Ethical and Professional Standards Committee shall also be enclosed. Ordinarily the respondent shall be informed of the name of the complainant, when written permission to do so has been obtained. (See Section III, C-5 above, for exception.)

B. The respondent shall be asked to provide a written statement outlining his/her view of the situation in order that the Committee may be cognizant of all relevant aspects of the case.

C. Whenever possible, the Ethical and Professional Standards Committee shall attempt to resolve differences privately and informally through further correspondence with all parties involved. An attempt shall be made to bring about an adjustment through mediative efforts in the interest of correcting a general situation or setting the particular issues between the parties involved.

D. If the respondent does not respond to the original inquiry within 30 days, a follow-up letter shall be sent to the respondent by registered or certified mail, marked "confidential," with a return receipt requested.

E. If the respondent refuses to reply to the Committee's inquiry or otherwise cooperate with the Committee, the Committee may continue its investigation, noting in the record the circumstances of the respondent's failure to cooperate. The Committee shall also inform the respondent that his/her lack of cooperation may result in action which could eventuate in his/her being dropped from membership in the Association.

F. As a rule, if the complainant wishes to withdraw the complaint, the inquiry is terminated, except in the extreme cases where the Committee feels the issues in the case are of such importance as to warrant completing the investigation in its own right and in the interest of the public welfare or that of the Association. (See Section III, C-5.)

G. The Association will not recognize a respondent's resignation from membership while there is a complaint pending before the Ethical and Professional Standards Committee or before an ethics committee of a state association unless he/she submits an affidavit stating that:

1. The resignation is free and voluntary;

2. He/she is aware of a pending investigation into allegations of misconduct;

3. He/she acknowledges that the material facts upon which the complaint is based are true; and;

4. He/she submits the resignation because he/she knows that if charges are predicated on the misconduct under investigation, he/she could not defend him/herself successfully against them.

H. Within 30 days of receipt of the written statement from the respondent, or (in the event the respondent fails to reply or otherwise cooperate), within 30 days of receipt of the return receipt requested from the second notification by the Committee (Section IV, D, E), the chairpersons, through advice of the Committee, shall determine if a violation may have occurred, and if so, what principles have potentially been violated.

I. If, in the opinion of the Committee, the complaint has a basis in fact but is considered likely to be corrected without further action, the chairpersons shall so indicate in the record and shall so inform all parties involved.

J. If, in the opinion of the chairpersons, the issues raised by the complaint would, if true, constitute a violation of the principles, and if it appears that the complaint cannot be resolved by less formal means, the chairpersons shall, in coordination with the appropriate State Delegate, appoint two impartial NASP members from the state in which the respondent practices to form an Ad Hoc Committee, together with the chairpersons of the Ethical and Professional Standards Committee. The purpose of this Ad Hoc Committee is to investigate the case, to evaluate the character of the behavior(s) in question, and to make recommendations to the Ethics and Professional Standards Committee for final disposition of the case.

K. The Ethical and Professional Standards Committee chairpersons shall transmit to the members of the Ad Hoc Committee, by registered or certified mail, in envelopes marked "confidential," copies of the following:

1. The original complaint or material;

2. The letter to the respondent apprising him/her of the nature of the alleged violation;

3. The response from the respondent; and

4. Any such further facts related to the case as the chairpersons can assemble from sources of evident reliability.

L. The Ad Hoc Committee shall then determine whether;

1. The case shall be closed;
2. Further investigation by correspondence is indicated;
3. Further investigation by a Fact-Finding Committee is indicated (see Section VI);
4. The respondent and/or complainant shall be asked to appear before the Ad Hoc Committee; or
5. Some other action or a combination thereof shall be taken.

Section V. Recommendations of the Ad Hoc Committee

A. When the Ad Hoc Committee has obtained sufficient information with which to reach a decision, or in any event, in not more than 60 days from the formation of the Ad Hoc Committee, the Ethical and Professional Standards Committee chairpersons shall request that the Ad Hoc Committee vote on the disposition of the case.

B. If, in the unanimous opinion of the Ad Hoc Committee members, a violation of the NASP Principles has occurred and if, in the opinion of the Ad Hoc Committee, the unethical behavior can be terminated by action of the Committee itself, one or more of the following recommendations shall be made:

1. The Ad Hoc Committee shall request, in writing, that the respondent take corrective measures to modify or stop certain activities or practices;
2. The Ad Hoc Committee shall, in writing, censure or reprimand the respondent;
3. The Ad Hoc Committee shall require that the respondent provide restitution to or apologize, in writing, to an individual, group of individuals, or organization harmed by the respondent's unethical conduct.
4. The Ad Hoc Committee shall recommend that the respondent be placed under a period of probation of membership or surveillance under fixed terms agreed to by the respondent;
5. The Ad Hoc Committee may recommend a combination of the above four recommendations. (NOTE — In all cases, supervision of the member's behavior for a period of time will be a required component of the corrective action.)

C. Within 5 days, the Ethical and Professional Standards Committee chairpersons shall inform the respondent of the Ad Hoc Committee's determination and recommendations. The respondent shall be notified that he/she may make a request for a hearing on the charges within 30 days from the receipt of a statement of the charges and the Committee's findings and recommendations. Such a request shall be in writing and directed to the President of the Association.

D. The Ethical and Professional Standards Committee chairpersons shall draft a report summarizing the findings and recommendations of the Ad Hoc Committee, copies of which shall be distributed to the two other Ad Hoc Committee members, the respondent, and, at the Committee's discretion, the complainant. This report shall be transmitted in envelopes marked "confidential" in the case of the respondent, by registered or certified mail with a return receipt requested.

E. A summary report shall then be edited by the Ethical and Professional Standards Committee chairpersons, ensuring the confidentiality of all persons involved is strictly maintained, for purposes of reporting to the Delegate Assembly at the next regularly scheduled meeting on the activities and recommendations of the Ethical and Professional Standards Committee and its designees, e.g., any Ad Hoc Committee so convened in the interim.

F. The unanimous decision by the Ad Hoc Committee shall be binding on the Association unless overturned by the Hearing Committee, Executive Board, or Delegate Assembly in accordance with the procedures outlined herein. (See Section VIII.)

Section VI. Conduct of a Formal Investigation

A. A formal investigation shall be undertaken if any one of the following circumstances prevails:

1. The Ad Hod Committee finds that it lacks sufficient data with which to proceed;
2. The Ad Hoc Committee is unable to reach consensus;
3. The recommendations of the Ad Hoc Committee do not lead to resolution of the problem; or
4. The facts alleged in the complaint, if substantiated, would likely require action leading to termination of the respondent's membership in the Association, or revocation of a National Certificate.

B. When a formal investigation is warranted under these procedures, the Ethical and Professional Standards Committee chairpersons, in coordination with the President of the Association, shall appoint a Fact-Finding Committee, which shall appoint its own chairperson, to consist of not less than three nor more than five members of the Association, for the specific purpose of more fully investigating the charges. No member previously involved in reviewing the case may serve on the Fact-Finding Committee. The Ethical and Professional Standards Committee chairpersons shall serve on the Fact-Finding Committee in ex-officio status in order to apprise the Fact-Finding Committee of the procedures by which they are bound and to serve in an advisory capacity.

C. The Fact-Finding Committee shall be bound by the same procedures and timelines as outlined in Sections III and IV of these procedures. In addition, the Fact-Finding Committee may, at the discretion of the Executive Board, retain a legal advisor as counsel to the committee while investigating its case.

D. The respondent may seek advice from any individual, including an attorney or another member of the Association, for assistance in preparing and presenting documentary evidence requested by the Fact-Finding Committee.

Section VII. Recommendations of the Fact-Finding Committee

A. If the formal investigation was convened following a decision by consensus of the Ad Hoc Committee, and if the Fact-Finding Committee unanimously concurs with the Ad Hoc Committee's findings and recommendations, all parties shall be so informed and this decision shall be binding on the Association unless overturned by the Hearing Committee, Executive Board, or Delegate Assembly, in accordance with the procedures outlined herein.

B. If the case was not resolved at the Ad Hoc Committee level, the Fact-Finding Committee must announce its findings and recommendations within the prescribed timelines. The Fact-Finding Committee may exercise any of the recommendations open to the Ad Hoc Committee (Section V, B) and in addition may also recommend that the respondent's membership in the Association be terminated.

C. Should the Fact-Finding Committee so recommend, the chairpersons of the Ethical and Professional Standards Committee must present the findings and recommendations of the Fact-Finding Committee to the NASP Executive Board and Delegate Assembly. A summary report shall be prepared, such that the confidentiality of all parties involved, i.e., identifying information of the informer, is strictly maintained. The case shall be reviewed in sufficient detail so as to allow the Executive Board and the Delegate Assembly members to vote to concur or overrule the decision of the Fact-Finding Committee.

D. In accordance with NASP Bylaws, cases involving a recommendation for expulsion from the Association by the Ethical and Professional Standards Committee shall be confirmed by a 2/3 vote of the Executive Board, with a member of the NSPCS, the expulsion shall be reported to the NSPCB along with a recommendation for further action, if any, the NSPCB should take.

E. At the discretion of the Executive board and Delegate Assembly, the respondent may be allowed to voluntarily resign his/her membership in the Association.

F. Within five days, the Ethical and Professional Standards Committee chairpersons shall inform the respondent of the decision of the Executive Board and Delegate Assembly in the same manner as provided in Section V, C of these procedures.

G. If the Executive board and/or the Delegate Assembly do not concur with the Committee's recommendation for expulsion from membership, the case shall be remanded back to the Fact-Finding Committee for consideration of a lesser penalty.

Section VIII. Conduct of the Hearing Committee

A. Within 30 days of receipt of a statement of the charges against him/her and a statement of the Committee's findings and recommendations, the respondent has the right to request from the President of the Association a hearing on the charges. This right shall be considered waived if such request is not made in writing within the 30 day period.

B. If the respondent does request a hearing, the President shall select a panel of ten members of the Association, none of whom shall be members of the Ethical and Professional Standards Committee or have had any prior connection with the case. From the panel, the respondent shall have 30 days in which to choose a Hearing Committee of five members. If he/she does not make a selection, the President shall choose the five members to comprise the Hearing Committee.

C. The President shall select a chairperson of the Hearing Committee who shall conduct the hearing and assure that the procedures are properly observed. There shall be no communication between the members of the Hearing Committee and the Ethical and Professional Standards Committee or any of its representatives prior to the hearing itself.

D. A date for the hearing shall be set by the President with the concurrence of the respondent. In no event shall the hearing take place later than 90 days from the date of the respondent's request for a hearing.

E. At least 30 days prior to the hearing, the respondent and the Hearing Committee members shall be provided with copies of all documents to be presented and the names of all witnesses that will be offered by the Ethical and Professional Standards Committee in support of the charges.

F. Presentation of the case against the respondent shall be the responsibility of the Ethical and Professional Standards Committee, or such others as the Ethical and Professional Standards Committee has designated to investigate the complaint. Legal counsel for the Association may participate fully in the presentation of the case.

G. All evidence that is relevant and reliable, as determined by the chairperson of the Hearing Committee, shall be admissible. Evidence of mitigating circumstances may be presented by the respondent.

H. The respondent shall have the right to counsel, to present witnesses and documents, and to cross-examine the witnesses offered by the Ethical and Professional Standards Committee.

I. The hearing may be adjourned as necessary and the Ethical and Professional Standards Committee may introduce rebuttal evidence.

J. In the interest of obtaining a full and accurate record of the hearing, a tape recorder or other transcription device may be used, at the discretion of the Hearing Committee and the respondent.

Section IX. Recommendations of the Hearing Committee

A. At the conclusion of the hearing, the Hearing Committee shall have 30 days in which to issue its report and recommendations.

B. If the Hearing Committee recommends that the respondent be dropped from membership or that the respondent be permitted to resign, the matter shall be referred to the Executive Board. A recommendation that the respondent be expelled or be allowed to resign must be made by 4 of the 5 committee members. Other disciplinary measures would be decided upon per individual case and would require a simple majority vote.

C. Only the disciplinary measures specified by the Ethical and Professional Standards Committee in the formal statement of charges, or a lesser penalty, shall be recommended by the Hearing Committee. Although the Ethical and Professional Standards Committee recommendations may be modified by the Hearing Committee, it may not increase the penalty recommended.

D. The Hearing Committee shall submit its report and recommendations simultaneously to the Executive Board and to the respondent.

E. The respondent shall have 15 days from receipt of the Hearing Committee's report in which to file a written statement with the Executive Board. The Ethical and Professional Standards Committee shall then have 15 days in which to file a response.

F. After consideration of the record, the recommendations of the Hearing Committee and any statements that may be filed, the Executive Board shall adopt the recommendations of the Hearing Committee unless it determines that:

1. The NASP Principles and/or the procedures herein stated have been incorrectly applied;
2. The findings of fact of the Hearing Committee as stated in the report are not supported by the evidence, or;
3. The procedures followed were in violation of the Bylaws of the Association.

G. The Ethical and Professional Standards Committee shall inform the respondent and, at its discretion, may inform the complainant of any final action taken by the Executive Board. The Ethical and Professional Standards Committee shall report to the Delegate Assembly at its next regularly scheduled meeting, in Executive Session, the names of those members who have been allowed to resign or who have been expelled from membership, and the ethical principle(s) involved. Actions involving individuals who hold a certificate issued by the NSPCB will be reported to the national certification board in a timely manner.

H. The Ethical and Professional Standards Committee shall report annually and in confidence to the Delegate Assembly and Executive Board, in Executive Session, the names of members who have been expelled from the Association and the ethical principle(s) involved.

I. In severe cases and when the welfare of the public is at stake, and when the Ethical and Professional Standards Committee deems it necessary to maintain the principles of the Association and the profession, it may also notify affiliated state and regional associations and state and local licensing and certification boards of the final disposition of the case. Other interested parties, including the respondent's employer, may be notified of the final action when, in the opinion of the Ethical and Professional Standards Committee, notification is necessary for the protection of the public or the profession.

PROCEDURAL GUIDELINES FOR THE ADJUDICATION OF ETHICAL COMPLAINTS

A COMPLAINT IS RECEIVED BY THE COMMITTEE

Is the complaint anonymous?	If so, take no action.
Is the complaint oral?	If so, advise only.
Is the complaint about *Standards?*	If so, advise only.
Is the complaint frivolous or vengeful?	If so, consider action against complainant.
Is the ethical complaint about a NASP member or a member of the National Certification system?	If not, advise complainant that the situation is out of NASP jurisdiction.

WITHIN 15 DAYS OF THE COMPLAINT:

The committee reviews the written complaint.

Is there a potential violation of NASP ethics?	If not, notify complainant and get more information, or stop.

Complainant is advised that an informal investigation will occur, and is asked for a release so that respondent may know who issued the complaint.

Is the release obtained?	If not, the committee must decide whether to proceed on its own volition.

WITHIN 15 DAYS OF SIGNED RELEASE:

Inform the respondent, describe the complaint and the principles believed to be involved, request cooperation, and send a copy of the *Ethics*. Ask for a written response.

Attempt to resolve the situation informally, if possible.

IF NO ANSWER WITHIN 30 DAYS:

Follow up with another request for a written response, using a certified letter with return receipt requested.

If there is still no reply, or if the respondent refuses to cooperate, note this in the record and inform the respondent that a lack of cooperation could result in expulsion from NASP.

WITHIN 30 DAYS OF THE WRITTEN STATEMENT:

If the facts seem to suggest that a violation may have occurred, is the situation likely to correct itself without further action?	If so, inform all parties and monitor the situation.

WITHIN THE NEXT 60 DAYS:

Contact the state delegate, appoint two impartial NASP members in the respondent's state, and form an Ad Hoc committee.

Ad Hoc committee receives copies of the original complaint materials, the committee's letter to the respondent, the respondent's written response, and other pertinent material.

Can the situation be settled at the informal level?	If so, contact the parties and monitor the situation.
Can the needed information be obtained through correspondence?	If so, the Ad Hoc committee continues to gather the facts.
Does the Ad Hoc committee need for the complainant and the respondent to appear?	If so, arrange for them to appear before the committee.
Does the Ad Hoc committee have enough information to decide the issues at hand?	If not, begin fact finding procedures.
Is the Ad Hoc committee unanimous in its decision?	If not, begin formal investigation procedures.

THE COMMITTEE ISSUES A DECISION, WHICH IS BINDING
UNLESS OVERTURNED BY A HEARING;
SUPERVISION IS REQUIRED:

Order corrective action.	Censure or reprimand.	Require an apology or restitution	Require probation	Determine no violation occurred.

WITHIN 5 DAYS:

Notify the respondent of the decision.

WAIT 30 DAYS FOR RESPONDENT TO REQUEST A HEARING:

If there is no request for a hearing, draft a report and advise the Delegate Assembly of the actions of the committee. Make recommendations to National Certification Board if respondent holds national certification.

FORMAL INVESTIGATION PROCEDURES

Follow these steps if:

- The Ad Hoc committee lacks the data to proceed.
- The Ad Hoc committee cannot reach a consensus.
- The solutions available to the Ad Hoc committee are unlikely to resolve the problem.
- The facts, if substantiated, could lead to the expulsion of a NASP member or a member of the NSPCS.

The chairs of the Ethical and Professional Standards Committee, along with the NASP President, appoint members of a fact finding committee. This committee follows the same basic procedures as the Ad Hoc committee.

Does the fact finding committee concur unanimously with the Ad Hoc Committee?

If so, the Ad Hoc Committee decisions are binding unless overturned by a hearing, Executive Board, or Delegate Assembly.

The fact finding committee reaches its own conclusions. The recommendations may include expulsion.

If expulsion is advised, the Ethical and Professional Standards chairs will present the findings to the NASP Executive Board and the Delegate Assembly, with all due consideration for matters of confidentiality.

Is the expulsion recommendation confirmed by a 2/3rd vote of the Executive Board and ratified by a majority of the Delegates?

If not, have the fact finding committee review the situation and consider a lessor penalty.

WITHIN 5 DAYS:

Notify the respondent.

WAIT 30 DAYS FOR RESPONDENT TO REQUEST A HEARING:

If there is no request for a hearing, draft a report and advise the Delegate Assembly and the National Certification Board (if necessary) of the actions of the committee.

CONDUCT OF THE HEARING COMMITTEE

Upon receipt of a written decision by the Ad Hoc or the Fact Finding committee, a respondent has thirty days in which to ask for a hearing. Should a hearing be requested within the 30 days:

The NASP President selects a panel of 10 impartial NASP members. From this group, the respondent selects 5 to serve on the committee. The President then selects the Chair.

NO LATER THAN 90 DAYS FROM THE DATE OF THE HEARING REQUEST:

The date for the hearing is set.

AT LEAST 30 DAYS BEFORE THE HEARING:

Hearing committee members and respondent receive copies of all relevant documents.

AT THE HEARING:

The Ethical and Professional Standards committee chair, or designee, presents the facts in the complaint. The respondent has the right to counsel, to present witnesses and documents, and to cross-examine witnesses. The Ethical and Professional Standards committee may offer rebuttal.

WITHIN 30 DAYS:

The hearing committee issues a report and recommendations to the respondent and the NASP Executive Board.

WITHIN 15 DAYS:

The Ethical and Professional Standards Committee and the respondent may file comments on the hearing committee report.

AT THE NEXT EXECUTIVE BOARD MEETING:

Does the NASP Executive Board believe that there is no evidence of ethical misconduct, or that there was a problem with the application of the principles or procedures for investigation?

If yes, the matter is ended.

The Executive Board adopts the findings and recommendations of the Hearing Committee.

The Ethical and Professional Standards Committee informs the respondent, and has the discretion to inform the complainant or not. The EB/DA is notified of members expelled and the ethical principles involved. The National School Psychology Certification System will be notified if the proceedings involve an NSPCS member.

When the welfare of the public is at stake, NASP may notify other interested parties of the final disposition of the case.

Appendix II

Standards for the Provision of School Psychological Services

1.0 Definitions

1.1 A *School Psychologist* is a professional psychologist who has met all requirements for credentialing as stipulated in the appropriate NASP standards. The credential is based upon the completion of a school psychology training program which meets the criteria specified in the NASP *Standards for Training and Field Placement Programs in School Psychology.*

1.2 A *Supervising School Psychologist* is a professional psychologist who has met all NASP requirements for credentialing, and who has been designated by an employing agency as a supervisor responsible for school psychological services in the agency. Coursework or other training in the supervision of school personnel is desirable.

1.3 *Parent(s)*, as used in these *Standard*, includes both biological parent(s) and legal guardian(s) or appointed surrogates.

2.0 Standards for Administrative Agencies

The purpose of this section of the standards is to provide guidance to federal and state administrative agencies in regard to administrative organization, laws, policies, and regulations as they pertain to the provision of school psychological services.

2.1 Federal Level Administrative Agency

2.1.1. The federal education agency should employ a supervising school psychologist in order to accomplish the following objectives:

2.1.1.1 To provide professional leadership and assistance to the federal education agency, state education agencies, and the school psychology profession in regard to standards, policies, and procedures for program delivery, and for utilization, funding, education and training, and inservice education of school psychological services personnel.

2.1.1.2 To participate in the administration of federal programs providing funding for school psychological services in state, intermediate, and local education agencies, and for the education and training of school psychologists.

2.1.1.3 To encourage and assist in evaluation, research, and dissemination activities; to determine the effectiveness of school psychological education, training, and service programs; to determine needed changes; and to identify and communicate exemplary practices to training and service units.

2.1.1.4 To assure that consistent communication is established and maintained among professional organizations, federal, state, and local education agencies, and university training programs involved in providing and developing school psychological services.

2.1.2 Laws

2.1.2.1 The Congress of the United States should ensure that the rights of all parents and children are protected by the creation and modification of laws which provide for the services of school psychologists. These services include, but are not limited to, consultation, assessment, research, program planning/evaluation, and direct service for individuals, groups, and systems. These services should be available to all children, their families, and school personnel.

2.1.2.2 The Congress should ensure that school psychological services are provided in a free and appropriate manner to all children, their families, and school personnel in need of such services.

2.1.2.3 The Congress should ensure that federal laws recognize the appropriate involvement of school psychologists in educational programs and that adequate federal funding is made available for the education, training, services, and continuing professional development of school psychologists in order to guarantee appropriate and effective services.

2.1.2.4 The Congress should create no laws which effectively prohibit the credentialed school psychologist from the ethical and legal practice of his/her profession in the public or private sector, or which would be in violation of these standards.

2.1.3 Regulations

2.1.3.1 All federal agencies should utilize the services of the federal educational agency school psychologist in developing and implementing regulations pursuant to all relevant federal laws.

2.1.3.2 All federal agencies should seek the advice and consultation of the National Association of School Psychologists prior to the adoption of regulations pursuant to any federal law which involves or should reasonably involve the profession of school psychology.

2.1.3.3 Federal agencies should promulgate regulations consistent with the principles set forth in these *Standards* and the NASP *Principles for Professional Ethics*.

2.2 State Level Administrative Agencies

2.2.1 Organization. Each state educational agency (SEA) should employ at least one full-time supervising school psychologist for each 500 (or fewer) school psychologists within the state. An equivalent ratio should be maintained if there are more than 500 school psychologists. It is recognized that this ratio may vary based upon administrative structures, available resources, and types of programs served, however the intention is to assign the individual(s) full-time (1FTE) to the supervision of school psychology. Appropriate objectives to be accomplished by the SEA school psychologist(s) include the following:

2.2.1.1 To provide professional leadership assistance to the SEA, local educational agencies, and the profession with regard to standards, policies, and procedures for school psychology program delivery.

2.2.1.2 To support the utilization, funding, education, training, and in-service education of school psychologists.

2.2.1.3 To participate in the administration of state and federal programs providing funding for school psychological services in intermediate and local educational agencies, and for the education and training of school psychologists.

2.2.1.4 To encourage and assist in evaluation, research, and dissemination activities to determine the effectiveness of school psychological education, training, and service programs; to determine needed changes; and to identify and communicate exemplary practices to training and service units.

2.2.1.5 To maintain communication with and assure the input of state school psychological associations into the policy making of the SEA.

2.2.1.6 To communicate with the federal education agency school psychologist to ensure recognition of state issues and to facilitate input into federal policy.

2.2.2 Laws

2.2.2.1 All state legislative bodies should ensure that the rights of all parents and children are protected by the creation and modification of laws which provide for the services of school psychologists. These services include, but are not limited to, consultation for individuals, groups, and systems, assessment, program planning/evaluation, research, and direct service. These services are available to all children, their families, and school personnel.

2.2.2.2 The state legislature should ensure that school psychological services are provided in a free and appropriate way to all children, their families, and school personnel in need of such services.

2.2.2.3 The state legislature should ensure that state laws recognize the appropriate involvement of school psychologists in educational programs.

2.2.2.4 The state legislature should ensure that adequate funding is made available for the education, training, services, and continuing professional development of school psychologists in order to guarantee appropriate and effective services.

2.2.2.5 The state legislature should ensure that state laws provide for the credentialing of school psychologists consistent with NASP standards.

2.2.2.6 The state legislature should create no laws which prohibit the school psychologist from the ethical and legal practice of his/her profession in the public or private sector, or that prevent the school psychologist from practicing in a manner consistent with these *Standards*.

2.2.2.7 The state legislature should ensure that there are sufficient numbers of adequately prepared and credentialed school psychologists to provide services consistent with these *Standards*. In most settings, this will require at least one full-time school psychologist for each 1,000 children served by the LA, with a maximum of four schools served by one school psychologist. It is recognized that this ratio may vary based upon the needs of children served, the type of program served, available resources, distance between schools, and other unique characteristics.

2.3.3 Regulations

2.2.3.1 All state agencies should utilize the services of the SEA school psychologist(s) in developing and implementing administrative rules pursuant to all relevant state laws, federal laws, and regulations.

2.2.3.2 All state agencies should seek the advice and consultation of the state school psychologists' professional association prior to the adoption of rules pursuant to any state law, federal law, or regulation which involves or should reasonably involve the profession of school psychology.

2.2.3.3 All state education agencies should utilize the services of the SEA school psychologist(s) and the school psychologists' professional association in the SEA review and approval of school psychology training programs.

2.2.3.4 All state education agencies should utilize the services of the SEA school psychologist(s) and the school psychologists' professional association in developing and implementing administrative rules for credentialing school psychologists. Such rules shall be consistent with NASP *Standards for the Credentialing of School Psychologists*.

2.2.3.5 State education agencies should promulgate regulations consistent with the principles set forth in the *Standards* and the NASP *Principles for Professional Ethics*.

3.0 Standards for Employing Agencies

The purpose of these standards is to provide employing agencies with specific guidance regarding the organization, policies, and practices needed to assure the provision of adequate school psychological services.

3.1. Comprehensive Continuum of Services

Employing agencies assure that school psychological services are provided in a coordinated, organized fashion, and are deployed in a manner which ensures the provision of a comprehensive continuum of services as outlined in Section 4.0 of these *Standards*. Such services are available to all students served by the agency and are available to an extent sufficient to meet the needs of the population served.

Breadth or availability of services should not be dictated by the funding source. (For example, some Districts have been known to limit services to special education students only because the school psychology budget came from special education sources. Similarly, other Districts provided assessment services only because funds were taken from State or Federal assessment grants. Both cases are considered to be mistakes in the attempt to provide comprehensive school psychological services to all students.)

3.2 Professional Evaluation, Supervision, and Development

3.2.1 **Supervision**. Employing agencies assure that an effective program of supervision and evaluation of school psychological services exists. School psychologists, in cooperation with their employing agencies, are responsible for the overall development, implementation, and professional supervision of school psychological service programs, and are responsible for articulating those programs to others in the employing agency and to the agency's constituent groups.

3.2.2 **Supervisor(s).** The school psychological services program is supervised by a designated school psychologist who meets the requirements for a supervising school psychologist (Section 1.2) and who demonstrates competencies needed for effective supervision.

3.2.3 **Availability of Supervision.** Supervision is available to all school psychologists to an extent sufficient to ensure the provision of effective and accountable services (see Section 4.6 for specific requirements). In most cases, one supervising school psychologist should be employed for every ten school psychologists to be supervised (an equivalent ratio should be maintained for part-time supervisors). It is recognized that this ratio may vary based upon the type of program served, staff needs, and other unique characteristics.

3.2.4 **Intern Supervision.** A credentialed school psychologist meeting the requirements of a supervising school psychologist, with at least one year of experience at the employing agency, supervises no more than two school psychology interns at any given time (consistent with the NASP *Standards for Training and Field Placement Programs in School Psychology*), unless the supervising school psychologist has no other assigned duties. In such cases, a maximum of six school psychology interns may be supervised at any given time.

3.2.5 **Peer Review.** After initiating independent practice status (see Section 4.5), school psychologists continue to receive appropriate supervision. The independent practitioner should also engage in peer review with other school psychologists. Peer review involves mutual assistance with self-examination of services and the development of plans to continue professional growth and development. Employing agencies assure that school psychologists are given appropriate time and support for peer review activities.

3.2.6 **Accountability and Program Evaluation.** Employing agencies assure that school psychologists develop a coordinated plan for accountability and evaluation of all services provided in order to maintain and improve the effectiveness of services. Such plans include specific, measurable objectives pertaining to the planned effects of services on all relevant elements of the system. Evaluation and revision of these plans occurs on a regular basis.

3.2.7 **Continuing Professional Development.** Employing agencies recognize that all school psychologists, not just those holding national certification, are obligated to continue their professional training and development through participation in a recognized Continuing Professional Development (CPD) program (see Section 4.6). Employing agencies provide release time and financial support for such activities. They recognize documented continuing professional development activities in the evaluation and advancement of school psychologists. Private practitioners who contract to provide services are responsible for their own CPD program, and these activities should also be encouraged by employing agencies.

3.3 Conditions for Effective Service Delivery

In order to assure that employment conditions enable school psychologists to provide effective services, employing agencies adopt policies and practices ensuring that Section 3.3.1 through 3.3.4 are met.

3.3.1. School psychologists are not subjected to administrative constraints which prevent them from providing services in full accordance with these *Standards* and NASP *Principles for Professional Ethics*. When administrative policies conflict with these *Standards* or the NASP *Ethics*, the principles outlined in the *Standards* or *Ethics* take precedence in determining appropriate practices of the school psychologist.

3.3.2 School psychologists have appropriate input into the general policy making of the employing agency and the development of programs affecting the staff, students, and families they serve.

3.3.3 School psychologists have appropriate professional autonomy in determining the nature, extent, and duration of services they provide. Specific activities are defined within the profession, although school psychologists frequently collaborate and seek input from others in determining appropriate service delivery. Legal, ethical, and professional standards and guidelines are considered by the practitioner in making decisions regarding practice (see Section 4.4).

3.3.4 School psychologists have access to adequate clerical assistance, appropriate professional work materials, sufficient office and work space, and general working conditions that enhance the delivery of effective services. Included are test materials, access to private telephone and office, secretarial services, therapeutic aids, professional literature (books, journals), computers and related technology, and so forth.

3.4 Contractual Services

It is recognized that employing agencies may obtain school psychological services on a contractual basis in order to ensure the provision of adequate services to all children. However, each student within the educational system must be assured the full range of school psychological services necessary to maximize his/her success and adjustment in school. When an employing agency utilizes contractual services, the following standards are observed:

3.4.1. Contractual school psychological services encompass the same comprehensive continuum of services as that provided by regularly employed school psychologists. Overall, psychological services are not limited to any specific type of service and include opportunities for follow-up and continuing consultation appropriate to the needs of the student. Individual contracts for services may be limited as long as comprehensive services are provided overall.

3.4.2 Persons providing contractual psychological services are fully credentialed school psychologists as defined by these *Standards*. In specific limited instances, however, services by psychologists in other specialty areas (e.g., clinical, industrial/organizational) might be used to supplement school psychological services in a coordinated manner.

3.4.3 Contractual school psychological services are not to be utilized as a means to decrease the amount and quality of school psychological services provided by an employing agency. They may be used to augment programs but not to supplant them.

3.4.4 School psychologists providing contractual services are given appropriate access and information. They are familiar with the instructional resources of the employing agency to ensure that students they serve have the same opportunities as those served by regularly employed school psychologists.

3.4.5 Contractual school psychological services are provided in a manner which protects the due process rights of students and their parents as defined by state and federal laws and regulations.

3.4.6 Contracting for services is not to be used as a means to avoid legitimate employee rights, wages, or fringe benefits.

3.4.7 Psychologists providing contractual school psychological services provide those services in a manner consistent with these *Standards*, NASP *Principles for Professional Ethics*, and other relevant professional guidelines and standards.

3.4.8 Psychologists providing contractual school psychological services will encourage regular evaluation of the continued need for the service as well as the quality of the service.

3.5 Non-Biased Assessment and Program Planning

Employing agencies should adopt policies and practices in accordance with the following standards:

3.5.1 General Principles

3.5.1.1 School psychologists use assessment techniques to provide information which is helpful in maximizing student achievement, educational success, psychological adjustment, and behavioral adaptation.

3.5.1.2 School psychologists have autonomous decision-making responsibility (as defined in Section 4.4) to determine the type, nature, and extent of assessment techniques they use in student evaluation.

3.5.1.3 School psychologists have autonomy (as defined in Section 4.4) in determining the content and nature of reports.

3.5.1.4 Whenever possible, school psychologists use assessment techniques and instruments which have established validity and reliability for the purposes and populations for which the procedures are intended. In addition, certain clinical procedures and measures at the "research" stage of development may be used by practitioners trained in their use provided the reliability and validity of the procedures are reported and clearly distinguished from those techniques which meet standards.

3.5.1.5 School psychologists use, develop, and encourage assessment practices which increase the likelihood of the development of effective educational interventions and follow-up.

3.5.2 Professional Involvement

3.5.2.1 A multi-disciplinary team is involved in assessment, program decision-making, and evaluation. The team conducts periodic evaluations of its performance to ensure continued effectiveness.

3.5.2.2 The multi-disciplinary team includes a fully trained and certified school psychologist.

3.5.2.3 The school psychologist communicates a written minority position to all involved when in disagreement with the multi-disciplinary team position.

3.5.3 Non-Biased Assessment Techniques

3.5.3.1 Assessment procedures and program recommendations are chosen to maximize the student's opportunities to be successful in the general culture, while respecting the student's ethnic background.

3.5.3.2 Multifaceted assessment batteries are used which include a focus on the student's strengths.

3.5.3.3 Communications are held in the client's dominant spoken language or alternative communication system. All student information is interpreted in the context of the student's socio-cultural background and the setting in which she/he is functioning.

3.5.3.4 Assessment techniques (including computerized techniques) are used only by personnel professionally trained in their use and in a manner consistent with these *Standards.*

3.5.3.5 School psychologists promote the development of objective, valid, and reliable assessment techniques.

3.5.3.6 Interpretation of assessment results is based upon empirically validated research.

3.5.4 Parent/Student Involvement

3.5.4.1 Informed written consent of parent(s) and/or student (if the student has reached the age of majority) is obtained before assessment and special program implementation.

3.5.4.2 The parent(s) and/or student is fully informed of all essential information considered and its relevancy to decision-making.

3.5.4.3 The parent(s) and/or student is invited to participate in decision-making meetings.

3.5.4.4 The parent(s) and/or student is routinely notified that an advocate can participate in conferences focusing on assessment results and program recommendations.

3.5.4.5 A record of meetings regarding assessment results and program recommendations is available to all directly concerned.

3.5.5 Educational Programming and Follow-Through

3.5.5.1 School psychologists are involved in determining options and revisions of educational programs to ensure that they are adaptive to the needs of students.

3.5.5.2 The contributions of diverse cultural backgrounds should be emphasized in educational programs.

3.5.5.3 School psychologists follow-up on the efficacy of their recommendations.

3.5.5.4 Student needs are given priority in determining educational programs.

3.5.5.5 Specific educational prescriptions result from the assessment team's actions.

3.5.5.6 Where a clear determination of the student's needs does not result from initial assessment, a diagnostic intervention or teaching program is offered as part of additional assessment procedures.

3.5.5.7 Regular, systematic review of the student's program is conducted and includes program modifications as necessary.

3.6 School Psychological Records

3.6.1 The employing agency's policy on student records is consistent with state and federal rules and laws, and ensures the protection of the confidentiality of the student and his/her family. The policy specifies the types of data developed by the school psychologist which are classified as school or pupil records.

3.6.2. Parents may inspect and review any personally identifiable data relating to their child which were collected, maintained, or used in his/her evaluation. Although test protocols are part of the student's record, school psychologists protect test security and observe copyright restrictions. .

3.6.3 Access to psychological records is restricted to those permitted by law who have legitimate educational interest in the records.

3.6.4 School psychologists interpret school psychological records to non-psychologists who qualify for access.

3.6.5 School psychological records are only created and maintained when the information is necessary and relevant to legitimate educational program needs and when parents (or student if age of majority has been attained) have given their informed consent for the creation of such a record. This consent is based upon full knowledge of purposes for which information is sought, and the personnel who will have access to it. The school psychologist assumes responsibility for assuring the accuracy and relevancy of the information recorded.

3.6.6 School psychological records are systematically reviewed, and when necessary purged, in keeping with relevant federal and state laws in order to protect children from decisions based on incorrect, misleading, or out-of-date information.

4.0 Standards for the Delivery of Comprehensive School Psychological Services

The purpose of these standards is to ensure the delivery of comprehensive services by school psychologists.

4.1 Organization of School Psychological Services

4.1.1 School psychological services are planned, organized, directed, and reviewed by school psychologists.

4.1.2 School psychologists participate in determining the recipients and the type of school psychological services offered.

4.1.3 The goals and objectives of school psychological services are available in written form.

4.1.4 A written set of procedural guidelines for the delivery of school psychological services is followed and made available upon request.

4.1.5 A clearly stated referral system is in writing and is communicated to parents, staff members, students, and other referral agents.

4.1.6 The organization of school psychological services is in written form and includes lines of responsibility, supervisory, and administrative relationships.

4.1.7 Where two or more school psychologists are employed, a coordinated system of school psychological services is in effect within that unit.

4.1.8 Units providing school psychological services include sufficient professional and support personnel to achieve their goals and objectives.

4.2 Relationship to Other Units and Professionals

4.2.1 The school psychological services unit is responsive to the needs of the population that it serves. Psychological services are periodically and systematically reviewed to ensure their conformity with the needs of the population served.

4.2.2 School psychologists establish and maintain relationships with other professionals (e.g., pediatricians, bilingual specialists, audiologists) who provide services to children and families. They collaborate with these professionals in prevention, assessment, and intervention efforts as necessary. They also cooperate with advocates representing children and their families.

4.2.3 Providers of school psychological services maintain a cooperative relationship with colleagues and co-workers in the best mutual interests of clients, in a manner consistent with the goals of the employing agency. Conflicts should be resolved in a professional manner.

4.2.4 School psychologists develop plans for the delivery of services in accordance with best professional practices.

4.2.5 School psychologists employed within a school setting help coordinate the services of mental health providers from other agencies (such as community mental health centers, child guidance clinics, or private practitioners) to ensure a continuum of services.

4.2.6 School psychologists are knowledgeable about community agencies and resources. They provide liaison and consulting services to the community and agencies regarding psychological, mental health, and educational issues.

4.2.6.1 School psychologists communicate as needed with state and community agencies and professionals (e.g., child guidance clinics, community mental health centers, private practitioners) regarding services for children, families, and school personnel. They refer clients to these agencies and professionals as appropriate.

4.2.6.2 School psychologists are informed of and have the opportunity to participate in community agency staffings of cases involving their clients.

4.2.6.3 Community agency personnel are invited to participate in school system conferences concerning their clients (with written parental permission).

4.3 Comprehensive School Psychological Services Delivery

School psychologists provide a range of services to their clients. These consist of direct and indirect services which require involvement with the entire educational system: (a) the students, teachers, administrators, and other school personnel; (b) the families, surrogate caretakers, and other community and regional agencies, and resources which support the educational process; (c) the organizational, physical, temporal, and curricular variables which play major roles within the system; and (d) a variety of other factors which may be important on an individual basis.

The intent of these services is to promote mental health and facilitate learning. Comprehensive school psychological services are comprised of diverse activities. These activities complement one another and therefore are most accurately viewed as being integrated and coordinated rather than discrete services. However, for descriptive purposes, they will be listed and described separately. The following are the services that comprise the delivery system:

4.3.1 **Consultation:** the act of meeting to discuss, decide, or plan, typically regarding primary prevention or the reasons for an identified problem, and the resulting intervention(s). The school psychologist usually does not personally provide the intervention, but guides those who do. (See **direct service** for contrast.)

4.3.1.1 School psychologists consult and collaborate with parents, school, and outside personnel regarding mental health, behavioral, and educational concerns.

4.3.1.2 School psychologists design and develop procedures for preventing disorders, promoting mental health and learning, and improving educational systems.

4.3.1.3 School psychologists provide skill enhancement activities (such as inservice training, organizational development, parent counseling, program planning and evaluation, vocational development, and parent education programs) to school personnel, parents, and others in the community, regarding issues of human learning, development, and behavior.

4.3.1.4 School psychologists facilitate the delivery of services by assisting those who play major roles in the educational system (i.e., parents, school personnel, community agencies).

4.3.2 Psychological and Psychoeducational Assessment: the process of obtaining data about human functioning according to the current practices of the fields of psychology and education for the purpose of identifying critical factors and evaluating their importance for answering referral questions.

4.3.2.1 School psychologists conduct multifactored psychological and psychoeducational assessments of children and youth as appropriate.

4.3.2.2 Psychological and psychoeducational assessments include evaluation, as appropriate, of the areas of: personality, emotional status, social skills and adjustment, intelligence and cognitive functioning, scholastic aptitude, adaptive behavior, language and communication skills, academic knowledge and achievement, sensory and perceptual-motor functioning, educational setting, family/environmental-cultural influences, career and vocational development, aptitude, and interests.

4.3.2.3 School psychologists utilize a variety of instruments, procedures, and techniques. Interviews, observations, and behavioral evaluations are included in these procedures.

4.3.2.4 When conducting psychological and psychoeducational assessments, school psychologists have explicit regard for the context and setting in which their assessments take place and will be used.

4.3.2.5 School psychologists adhere to the NASP resolutions regarding non-biased assessment and programming for all students (see Section 3.5.3). They also are familiar with and consider the *Standards for Educational and Psychological Tests* (developed by APA, AERA, and NCME) and other related publications in the use of assessment techniques.

4.3.3 Direct Service: techniques applied in a face-to-face situation designed to enhance the mental health, behavior, personality, social competency, academic or educational status of the student/client. (Contrast with **consultation.**)

4.3.3.1 School psychologists provide direct service to facilitate the functioning of individuals, groups, and/or organizations.

4.3.3.2 School psychologists design direct service programs to enhance cognitive, affective, social, and vocational development.

4.3.3.3 School psychologists develop collaborative relationships with their clients and involve them in the assessment, direct service, and program evaluation procedures.

4.3.4 Supervision: the process of overseeing and managing the activities of a school psychologist for the purpose of quality assurance, assistance with difficult assignments, and the improvement of performance.

4.3.4.1 School psychologists provide and/or engage in supervision, peer review, and continuing professional development as specified in Section 3.2 and 4.6.

4.3.5 **Research:** the process of careful, systematic investigation to discover or establish facts.

4.3.5.1 School psychologists design, conduct, report, and utilize the results of research of a psychological and educational nature. All research conducted is in accordance with relevant ethical guidelines of the profession (e.g., APA *Ethical Principles in the Conduct of Research with Human Participants)*, with particular concern for obtaining informed consent, notifying subjects of the expected length of participation, and protecting subjects from breach of confidentiality, coercion, harm, or danger. Applied and/or basic research should be pursued, focusing on:

(a) psychological functioning of human beings;

(b) Psychoeducational assessment tools and procedures;

(c) Educational programs and techniques applied to individual cases and groups of various sizes;

(d) Educational processes;

(e) Social system interactions and organizational factors associated with school communities; and

(f) Psychological treatments and techniques applied to individual cases or groups.

4.3.5.2 School psychologists' involvement in research can range from support or advisory services to having direct responsibility for one or more major components of a research project. These components may include planning, data collection, data analyzing, disseminating, and translating research into practical applications within the school community.

4.3.6 **Program Planning and Evaluation:** the process of designing and judging the effectiveness of educational structures at all levels.

4.3.6.1 School psychologists provide program planning and evaluation services to assist in decision-making activities.

4.3.6.2 School psychologists serve on committees responsible for developing and planning educational and educationally-related activities.

4.4 Autonomous Functioning

School psychologists have professional autonomy in determining the nature, scope, and extent of their specific services. These activities are defined within the profession, although school psychologists frequently collaborate with and seek input from others in determining appropriate services delivery. Legal, ethical, and professional standards and guidelines are considered by the practitioner in making decisions regarding practice. All practice is restricted to those areas in which the school psychologist has received formal training and supervised experience.

4.4.1 **Professional Responsibility and Best Practices**. Professional autonomy is associated with professional responsibility. The ultimate responsibility for providing appropriate comprehensive school psychological services rests with the individual practitioner.

While being cognizant of the fact that there often are not explicit guidelines to follow in providing comprehensive school psychological services, the individual practitioner has a responsibility to adhere to the best available and most appropriate standards of practice. There is no substitute for sensitive, sound, professional judgment in the determination of what constitutes best practice. Active involvement in supervision and other continuing professional development activities will assist the practitioner in adhering to best professional practices.

4.5 Independent Practice

A credentialed school psychologist who has completed a school psychology training program which meets the criteria specified in the NASP *Standards for Training and Field Placement Programs in School Psychology* and three years of satisfactory, properly supervised experience is considered qualified for unsupervised practice with peer review, regardless of work setting. (NOTE: "independent practice" as used in this paragraph refers to the character of supervision needed. Contrast this with the licensure rules various states have for "private practice.")

4.6 Continuing Professional Development

The practice of school psychology has and will continue to undergo significant changes as new knowledge and technological advances are introduced. The development of new intervention techniques, assessment procedures, computerized assistance, and so forth, will require that practitioners keep abreast of these innovations as well as obtain appropriate professional education and training in these areas. All school psychologists actively participate and engage in activities designed to continue, enhance, and upgrade their professional training and skills and to help ensure quality service provision. These efforts are documented by participation in the NASP or other formal Continuing Professional Development (CPD) programs, although they are not limited to such activities. Memberships in professional organizations, reading of professional journals and books, discussions of professional issues with colleagues, and so forth, are also an integral component of a school psychologist's overall CPD activities.

4.6.1 Participation in CPD activities and the maintenance of high professional standards and practice are continuing obligations of the school psychologist. These obligations are assumed when one initially engages in the practice of school psychology and should be required for continued credentialing.

4.6.2 School psychologists receive supervision by a supervising school psychologist for the first three years of full-time employment (or the equivalent) as a school psychologist. The supervisor shares professional responsibility and accountability for the services provided. While the level and extent of supervision may vary, the supervisor maintains a sufficiently close relationship to meet this standard. Individual face-to-face supervision is engaged in for a minimum of one hour per week or the equivalent (e.g., two hours bi-weekly). Standards for intern supervision are contained in the NASP *Standards for Training and Field Placement Programs in School Psychology.*

4.6.3 After completion of the first three years of supervision, all school psychologists continue to engage in supervision and/or peer review on a regular basis, and further their professional development by actively participating in CPD activities. The level and extent of these activities may vary depending on the needs, interests, and goals of the school psychologist, with more comprehensive service delivery requiring more extensive related professional exchanges. At a minimum, however, these activities are at the level required for successful participation in an appropriate CPD program.

4.6.4 School psychologists, who after three years no longer have required supervision, engage in peer review activities. These may include discussion of cases and professional issues designed to assist with problem solving, decision-making, and appropriate practice.

4.6.5 School psychologists readily seek additional assistance from supervisors, peers, or colleagues with particularly complex or difficult cases, and/or when expanding their services into new areas or those in which they infrequently practice (e.g., low incidence assessment).

4.6.6 Nationally Certified School Psychologists engage in continuing professional development as a requirement of certificate renewal.

4.7 Accountability

4.7.1 School psychologists perform their duties in an accountable manner by keeping records of these efforts, evaluating their effectiveness, and modifying their practices and/or expanding their services as needed.

4.7.2 School psychologists devise systems of accountability and outcome evaluation which aid in documenting the effectiveness of intervention efforts and other services they provide.

4.7.3 Within their service delivery plan, school psychologists include a regular evaluation of their progress in achieving goals. This evaluation should include consideration of the cost effectiveness of school psychological services in terms of time, money, and resources, as well as the availability of professional and support personnel. Evaluation of the school psychological delivery system is conducted internally, and when possible, externally as well (e.g., through state educational agency review, peer review). This evaluation includes an assessment of effectiveness, efficiency, continuity, availability, and adequacy of services.

4.7.4 School psychologists are accountable for their services. They should make information available about their services, and provide consumers with the opportunity to participate in decision-making concerning such issues as initiation, termination, continuation, modification, and evaluation of their services. Rights of the consumer should be taken into account when performing these activities.

4.8 Private Practice

4.8.1 School psychologists practicing in the private sector provide comprehensive services and adhere to the same standards and guidelines as those providing services in the public sector.

4.8.2 School psychologists document that they have formal training, supervised experience, licensure and/or certification, and demonstrated competence, in any areas of service they intend to deliver to clients within the private sector. They also have a responsibility to actively engage in CPD activities.

4.8.3 School psychologists in private practice adhere to the NASP *Principles for Professional Ethics*, and practice only within their area of competence. If the services needed by clients fall outside the school psychologist's area of competence, they are referred elsewhere for assistance.

4.8.4 It is the responsibility of the school psychologist engaging in private practice to inform the client that school psychological services are available without charge from the client's local school district.

4.8.5 School psychologists do not provide services on a private basis to students who attend the school(s) to which the school psychologist is assigned, or would normally be expected to serve. This includes students who attend non-public schools served by the school psychologist.

4.8.6 School psychologists offering school psychological services in the private sector ensure that, prior to the commencement of treatment/services, the client fully understands any and all fees associated with the services, and any potential financial assistance that may be available (i.e., third-party reimbursement).

4.8.7 Parents must be informed by the school psychologist that if a private school psychological evaluation is to be completed, this evaluation constitutes only one portion of a multi-disciplinary team evaluation. Private services must be equally comprehensive to those described in Section 4.3

4.8.8 School psychologists in private practice provide and maintain written records in a manner consistent with Section 3.6.

4.9 Professional Ethics and Guidelines

Each school psychologist practices in full accordance with the NASP *Principles for Professional Ethics*, and these *Standards*.

5.0 Standards for School Psychology Training Programs

Each school psychology training program should meet the criteria specified in the NASP *Standards for Training and Field Placement Programs in School Psychology*.

Appendix III

Standards for Training and Field Placement Programs in School Psychology (1994)

The National Association of School Psychologists (NASP) is committed to the development of comprehensive and effective psychological services for all children and youth. The NASP *Standards for Training and Field Placement Programs in School Psychology* contribute to the development of services through the identification of critical content and training experiences needed by students preparing for careers in school psychology. These *Standards* serve to guide the design of school psychology graduate education, as a basis for program evaluation, and as the foundation for the recognition of strong programs through the program approval process.

I. VALUES AS A PROGRAM FOUNDATION

As a specialty within the profession of psychology, school psychology is founded in respect for the dignity and worth of each individual and in a commitment to further the understanding of human behavior for the purpose of promoting human welfare. The values that serve as a foundation for this field should also provide a foundation for graduate education and professional practice in school psychology.

1.1 Standard: A commitment to understanding and responsiveness to human diversity is articulated and practiced throughout all aspects of the program, including admissions, faculty, coursework, practica, and internship experiences. Human diversity is recognized as a strength which is valued and respected. The program promotes recognition and valuing of the uniqueness of each individual, an affirmation of the inherent worth of all human beings, and a commitment to the enhancement of human development and capability through the application of school psychological services.

1.2 Standard: The program fosters a commitment to enhancing the strengths of critical socialization institutions such as families and schools through the delivery of school psychological services that are sensitive to the unique needs of systems and organizations, as well as effective in promoting mental health and the acquisition of competencies.

II. KNOWLEDGE BASE, TRAINING PHILOSOPHY, GOALS & OBJECTIVES

The essential knowledge base for the professional practice of school psychology encompasses psychological foundations, educational foundations, interventions and problem solving, statistics and research methodologies, and professional school psychology. That knowledge base should be delivered within a context of commonly held and publicly known values, and clearly articulated training philosophy, goals, and objectives for the preparation of future school psychologists. The same knowledge base standards apply to both specialist-level and doctoral programs. However, there shall be a clear distinction between the two levels. Additionally, doctoral programs shall ensure greater breadth or depth in each of the areas.

2.1 Standard: An integrated and sequential program of study and supervised practice shall be provided to all trainees that reflect the values and training philosophy of the program, ensuring the preparation of all trainees in accordance with clearly articulated goals and objectives. There shall be a direct and obvious relationship between the components of the curriculum and the goals and objectives of the program.

NOTE: The specification of content areas in Standards 2.2–2.8 does not necessarily require that an entire graduate-level course be devoted to each of the areas. The criterion for program approval purposes will be "substantive" preparation in each of the areas. Substantive preparation, depending on the area and the organization of the program, may mean an entire course, portions of one or more courses, didactic components of practica or internship, or practica or internship experiences.

2.2 Standard: Psychological Foundations

The program employs a systematic process that ensures that all students have a foundation in the knowledge base for the discipline of psychology. That knowledge base shall include:

Biological Bases of Behavior (e.g., biological bases of development, neuropsychology, physiological psychology, psychopharmacology)

Human Learning

Social and Cultural Bases of Behavior (e.g., cross-cultural studies, social development, social and cultural diversity, social psychology)

Child and Adolescent Development

Individual Differences (e.g., human exceptionalities, developmental psychopathology)

2.3 Standard: Educational Foundations

The program employs a systematic process that ensures that all students have a foundation in the knowledge base for education. That knowledge base shall include:

Instructional Design

Organizational and Operation of Schools (including, but not limited to, education of exceptional learners, school and community-based resources, alternative service delivery systems)

2.4 Standard: Interventions/Problem Solving

The Program employs a systematic process that ensures that all students possess the knowledge and professional expertise to collaborate with families and school- and community-based professionals in designing, implementing, and evaluating interventions that effectively respond to the educational and mental health needs of children and youth. Areas of knowledge and practice shall include:

Assessment (diverse models and methods linked to direct and indirect interventions)

Direct Interventions, both Individual and Group (including counseling and behavior management)

Indirect Interventions (including consultation, systems and organizational change)

2.5 Standard: Statistics and Research Methodologies

The program employs a systematic process that ensures that all students are competent consumers of research and new knowledge, and are able to use diverse methodologies (e.g., ethnographic, single subject designs, quantitative methods) to evaluate professional practices (e.g., interventions) and/or programs. That knowledge base shall include:

Research and Evaluation Methods
Statistics
Measurement

2.6 Standard: Professional School Psychology

The Program employs a systematic process that ensures that all students have a knowledge base specific to the professional specialty of school psychology. That knowledge base shall include:

History and Foundations of School Psychology
Legal and Ethical Issues
Professional Issues and Standards
Alternative Models for the Delivery of School Psychological Services
Emergent Technologies
Roles and Functions of the School Psychologist

III. PRACTICA

Practica are an essential component in the professional preparation of school psychologists. They provide opportunities for students to practice, under supervision, the application of knowledge and specific skills in the resolution of individual, group, and system-level problems. Practica are consistent with the values and training model of the program. Laboratory or field-based practica are used to evaluate a trainee's mastery of distinct skills as one measure of preparedness to enter the internship.

3.0 Standard: The program provides a sequence of closely supervised practica experiences through which students practice and are evaluated regarding their mastery of distinct skills consistent with the goals and objectives of the program. Practica include, but are not necessarily limited to, orientation to the educational process, assessment for intervention, direct intervention methods including counseling and behavior management, and indirect intervention methods including consultation.

Practica reflect the following characteristics:

a. Practica experiences shall include: (1) orientation to the educational process; (2) assessment for intervention; (3) direct intervention (including counseling and behavior management); and (4) indirect intervention (including consultation). Student performance shall be systematically evaluated in each area.

b. Practica experiences shall be distinct from and occur prior to the internship.

c. Practica occur at time(s), are in settings, and are of sufficient length to be appropriate to the specific training objectives of the program.

d. There is a direct and obvious relationship between practica experiences and the objectives for which the practica are intended.

e. Practica experiences occur under conditions of supervision appropriate to the specific training objectives of the program.

f. Practica experiences are provided appropriate recognition through the awarding of academic credit.

g. Practica experiences occur with university involvement appropriate to the specific training objectives of the program.

h. The quality of practica experiences are systematically evaluated in a manner consistent with the specific training objectives of the program.

i. Practica experiences are conducted in accordance with current legal-ethical standards for the profession.

IV. INTERNSHIP

The internship is the culminating experience in school psychology graduate preparation. It is a comprehensive experience through which the student is required to integrate the knowledge base and applied skills of school psychology in promoting positive educational and mental health practices and in resolving individual, group, and system-level problems. The internship affords the student the opportunity to demonstrate knowledge and skills acquired through coursework and practica, as well as to acquire new knowledge and skills. Internship settings shall be appropriate for the goals and objectives of the training program; all students shall complete at least one-half of their internship in a school setting. (See Standard 6.10).

4.0 Standard: A comprehensive internship experience is provided through which all students are required to demonstrate, under supervision, their ability to integrate knowledge and skills in providing a broad range of school psychological services. The internship is conceptualized as the culminating component in school psychology graduate education. It affords the student the opportunity to work with diverse client populations, a range of problems, and different types of human service programs, using varied intervention methodologies.

The internship experience reflects the following characteristics:

a. The internship experience is provided at or near the end of the formal training period.

b. The internship experience occurs on a full-time basis over a period of one academic year, or on a half-time basis over a period of two consecutive academic years.

c. The internship experience is designed according to a written plan that provides the student opportunities to gain experience in the delivery of a broad range of school psychological services. Services include, but are not limited to assessment for intervention, counseling, behavior management, and consultation.

d. The internship experience occurs in a setting appropriate to the specific training objectives of the program.

e. The internship experience is provided appropriate recognition through the awarding of academic credit.

f. The internship experience occurs under conditions of appropriate supervision. Field-based internship supervisors hold a valid credential as a school psychologist for that portion of the internship that is in a school setting. That portion of the internship which appropriately may be in a non-school setting requires supervision by an appropriately credentialed psychologist.

g. Field-based internship supervisors are responsible for no more than two interns at any given time. University internship supervisors are responsible for no more than twelve interns at any given time.

h Field-based internship supervisors provide, on average, at least two hours per week of direct supervision for each intern.

i. The internship is based on a positive working relationship and represents a collaborative effort between the university program and field-based supervisors to provide an effective learning experience for the student. University internship supervisors provide at least one on-site contact per semester with each intern and supervisor.

j. The internship placement agency provides appropriate support for the internship experience including: (a) a written contractual agreement specifying the period of appointment and the terms of compensation, (b) a schedule of appointment consistent with that of agency school psychologists (e.g., calendar, participation in in-service meetings, etc.), (c) provision for participation in continuing professional development activities, (d) expense reimbursement consistent with policies pertaining to agency school psychologists, (e) an appropriate work environment including adequate supplies, materials, secretarial services, and office space, (f) release time for internship supervisors, and (g) a commitment to the internship as a training experience.

k. The quality of the internship experience is systematically evaluated in a manner consistent with the specific training objectives of the program.

l. The internship experience is conducted in a manner consistent with the current legal-ethical standards of the profession.

V. PERFORMANCE-BASED PROGRAM ACCOUNTABILITY

Systematic evaluation of coursework, practica, internship experiences, faculty, supervisors, and institutional resources is essential to monitoring and improving program quality. It is essential that programs also demonstrate accountability with regard to the overall effectiveness of the total curriculum. That accountability is demonstrated through the ability of the program's graduates to provide school psychological services that effectively respond to the educational and mental health needs of children and youth, their families, and the educational and mental health agencies that serve them.

5.1 Standard: Systematic evaluation procedures are used to ensure the integrity and quality of the program. Different sources of information (e.g., tests of knowledge, observations of skills, instructional evaluation, performance portfolios, perceptions of students or supervisors), are used, as appropriate, to evaluate components of the program.

5.2 Standard: The program employs a systematic process to ensure that all students, prior to the conclusion of the internship experience, are able to integrate domains of knowledge and applied professional skills in delivering a comprehensive range of services that result in measurable positive changes regarding the educational and mental health needs of children and youth.

5.3 Standard: The program systematically collects, analyzes, and interprets process and performance evaluation data; results are used to improve the program.

VI. PROGRAM LEVEL AND STRUCTURAL REQUIREMENTS

Standards 6.1–6.5 Apply to Both Doctoral and Specialist-Level Programs

6.1 Standard: The program shall limit the number of credit hours acquired through courses, seminars, and other learning experiences not open exclusively to graduate students to no more than one-third of the student's program.

6.2 Standard: Program requirements exclude credit for undergraduate study, study which is remedial, or study which is designed to remove deficiencies in meeting requirements for program admission.

6.3 Standard: A full-time continuous residency or an alternate planned experience is required for all students. Programs allowing alternate planned experiences as a substitute for full-time residency must demonstrate how those experiences are equivalent to experiences commonly associated with residency requirements.

6.4 Standard: The program shall provide an active continuing professional development program for practicing school psychologists.

6.5 Standard: The program shall meet established approval standards for the appropriate state credentialing body(ies).

Requirements for Specialist-Level Programs (6.6–6.7)

6.6 Standard: Specialist-level programs shall consist of a minimum of three years of full-time study or the equivalent at the graduate level. The program shall include at least 60 graduate semester hours or the equivalent, at least 54 hours of which are exclusive of credit for the supervised internship experience. Institutional documentation of program completion shall be provided.

6.7 Standard: Specialist-level programs shall include at least one academic year of supervised internship experience, consisting of a minimum of 1200 clock hours, at least one-half of which must be in a school setting.

Requirements for Doctoral Programs (6.8–6.10)

6.8 Standard: Doctoral programs shall provide greater breadth and depth in knowledge domains and applied competencies. NOTE: Doctoral programs are encouraged to provide opportunities for doctoral study for practicing school psychologists and to allow credit for prior training to the greatest extent possible.

6.9 Standard: Doctoral programs shall consist of a minimum of four years of full-time study or the equivalent at the graduate level. The program shall include a minimum of 90 graduate semester hours or the equivalent, at least 78 of which are exclusive of credit for the predoctoral supervised internship experience and any terminal doctoral project (e.g., dissertation) and shall culminate in institutional documentation.

6.10 Standard: Doctoral programs shall include at least one academic year of predoctoral supervised internship experience, consisting of a minimum of 1500 clock hours, at least one-half of which must be in a school setting.

NOTE: Doctoral students who have met the school-based internship requirement through a specialist-level internship or equivalent experience may complete the predoctoral internship in a non-school setting. Program policy shall specifically define equivalent experiences and explain their acceptance with regard to doctoral internship requirements. Demonstration of policy implementation in practice also shall be provided.

Standards for the Credentialing of School Psychologists (1994)

Credentialing is the process which authorizes the use of the title School Psychologist, or related titles, by those professionals meeting accepted standards of training and experience who seek to provide school psychological services. The purpose of this document is to provide guidelines to state and national bodies for the establishment of, and procedural processes involved in, implementing credentialing standards. These guidelines were developed and approved by the National Association of School Psychologists (NASP) pursuant to its mission to further the mental health and educational development of children and youth and to advance the standards of the profession of school psychology.

The National School Psychology Certification System (NSPCS) was created by NASP to establish a nationally recognized standard for credentialing school psychologists. The title to be used by persons accepted into the NSPCS is Nationally Certified School Psychologist, or NCSP. Among the purposes of this national credentialing system are to promote uniform credentialing standards across states, agencies, and training institutions, and to facilitate credentialing of school psychologists across states through the use of reciprocity or equivalence. The NASP *Standards for the Credentialing of School Psychologists* are used by the NSPCS and are considered to be appropriate for states to use in executing their authority in credentialing school psychologists.

CREDENTIALING STRUCTURE

1. Legal Basis for Credentialing

   1.1 Credentialing is the process whereby a state authorizes the provision of school psychological services and the use of the title School Psychologist (or related titles such as School Psychology Specialist) by professionals meeting acceptable standards of training and experience. The basis of a state's credentialing authority is found in its statutory laws, whereby all providers of school psychological services and all users of the title School Psychologist must hold a current credential, and legal sanctions and sanctioning procedures are provided for violators.

2. Credentialing Body

   2.1 The state legislature shall empower one or more bodies to administer the credentialing (certification and/or licensure) process. Administrative codes and regulations adopted by such bodies shall comply with these *Standards for the Credentialing of School Psychologists*, and shall carry the weight of law.

3. Nature of the Credential

   3.1 The credential shall be issued in writing and expressly authorize both the practice of school psychology and the exclusive use of the title School Psychologist in all settings, public and private.

   3.2 The credential shall allow for the practice of school psychology as defined by NASP's *Standards for the Provision of School Psychological Services* (1992) in public and private settings (e.g., school, educational, mental health-related, or university-based child study clinics).

   3.3 Where a state empowers more than one body to issue more than one type of credential, such as for the separate regulation of school psychological services in the public schools and in private practice, the lowest entry levels of all such credentials shall conform to these standards.

CREDENTIALING REQUIREMENTS

4. Criteria for Credential

   4.1 The minimum requirement for credentialing shall be a sixth year/specialist program, with a 60 graduate semester hour minimum, consisting of coursework, practica, internship, and an appropriate graduate degree from an accredited institution of higher learning. Criteria for *each area shall be consistent with* NASP's *Standards for Training and Field Placement Programs in School Psychology* (1994).

4.2 The credentialing criteria shall require that competency be demonstrated in three areas: professional work characteristics, knowledge base, and applied professional practice. Each area is listed below and detailed in NASP's *Standards for Training and Field Placement Programs in School Psychology* (1994).

4.3 Professional Work Characteristics

The applicant's professional work characteristics shall be evaluated and verified by the applicant's school psychology training program through information collected during courses, practica, internship, and other appropriate means. Professional work characteristics shall include:

1. Communication Skills
2. Effective Interpersonal Relations
3. Ethical Responsibility
4. Flexibility
5. Initiative and Dependability
6. Personal Stability
7. Respect for Human Diversity

4.4 Knowledge Base

The applicant shall complete an integrated and sequential program of study that is explicitly designed to develop knowledge and competencies in the domains of psychological foundations, educational foundations, intervention and problem-solving, statistics and research methodologies, and professional school psychology.

Psychological Foundations

The applicant for the credential has a foundation in the knowledge base for the discipline of psychology, including:

Biological Bases of Behavior (e.g., biological bases of development, neuropsychology, psychopharmacology, physiological psychology)

Human Learning

Social And Cultural Bases of Behavior (e.g., social development, social and cultural-diversity, social psychology, cross-cultural studies)

Child and Adolescent Development

Individual Differences (including human exceptionalities and developmental psychopathology)

Educational Foundations

The applicant for the credential has a foundation in the knowledge base for education, including:

Instructional Design

Organization and Operation of Schools (including, but not limited to, education of exceptional learners, school- and community-based resources, alternative service delivery systems)

Intervention/Problem-Solving

The applicant for the credential has demonstrated knowledge and professional expertise to collaborate with families, schools, and community-based professionals in designing, implementing, and evaluating interventions that effectively respond to the educational and mental health needs of children and youth.

Assessment (diverse models and methods linked to direct and indirect interventions)

Direct Interventions (individual and group, including counseling and behavior management)

Indirect Interventions (including consultation, systems, and organizational change)

Statistics and Research Methodologies

The applicant for the credential is a competent consumer of research and new knowledge, and is able to use diverse methodologies (e.g., ethnographic, single-subject designs, quantitative methods) to evaluate professional practices (e.g., interventions) and/or programs.

Research and Evaluation Methods

Statistics

Measurement

Professional School Psychology

The applicant for the credential has a knowledge base specific to the professional specialty of school psychology and is able to demonstrate the application of that knowledge base to professional practice, including:

History and Foundations of School Psychology

Legal and Ethical Issues

Professional Issues and Standards

Alternative Models for Delivery of School Psychological Services

Emergent Technologies

Roles and Functions

4.5 Applied Professional Practice

The applicant shall provide written evidence of his/her ability to perform competently as a school psychologist. Such evidence shall consist minimally of successful completion and documentation of practicum experience and internship consistent with criteria outlined in NASP's *Standards for Training and Field Placement Programs in School Psychology* (1994).

A. The practica shall consist of a sequence of supervised experiences that occur prior to internship, are conducted in laboratory or field-based settings, and provide for application of knowledge and mastery of distinct skills.

B. The internship experience shall consist of a full-time experience over one year, or half-time over two years, with a minimum of 1200 clock hours, at least one-half of which must be in a school setting. Other acceptable internship experiences include private, state-approved educational programs, or other appropriate mental health-related programs or settings for the education of children and youth.

C. Other practicum and internship criteria are outlined in NASP's *Standards for Training and Field Placement Programs in School Psychology* (1994).

IMPLEMENTATION OF CREDENTIALING PROCEDURES

Only graduates from NASP approved training programs, or programs consistent with NASP training standards, shall be eligible for credentialing. A complete listing of NASP approved programs, *Approved Programs in School Psychology*, is published annually. Each approved program shall be responsible for assessing a candidate's competency in the areas of professional work characteristics, knowledge base, and applied professional practice. The responsibility for the final determination of minimum professional competencies in all credentialing areas, however, rests with the credentialing body. All assessment methods by both the training program and the credentialing body shall rely on the most objective, quantifiable, and accountable procedures available.

5. Type of Credential - State and National

5.1 State Credential

The state credential shall be granted to individuals who meet the requirements described in Standard 4, including an appropriate graduate degree, professional work characteristics, knowledge base, and applied professional practice.

Upon initial granting of the credential, the individual shall arrange supervision and mentoring to assure that entry level qualifications are translated into ongoing competency in the provision of school psychological services. Supervision shall consist of a minimum of one face-to-face contact hour per week or two consecutive face-to-face contact hours once every two weeks for the initial academic year of full time practice, or the equivalent. Supervision and mentoring shall be provided by a school psychologist with a minimum of three years of experience. For any portion of the experience which is accumulated in a non-school setting, supervision and mentoring shall be provided by a psychologist or school psychologist appropriately credentialed for practice in that setting.

Subsequent to the completion of the supervision requirement, an individual holding the credential shall participate in an organized program of continuing professional development.

Upon completion of the initial year of post-degree supervision, the credential shall allow psychologists to have professional autonomy in determining the nature, scope, and extent of their specific services in all settings, public and private. These services shall be consistent with the NASP definitions of school psychological services and shall be delivered within the bounds of the school psychologist's training, supervised experience, and demonstrated expertise as specified in NASP's *Standards for the Provision of School Psychological Services* (1992) and *Principles for Professional Ethics* (1992).

Individual states may choose to grant a continuing credential to persons who have met the criteria for supervision and continuing professional development, and have a minimum of three years of experience.

5.2 Nationally Certified School Psychologist

BEST COPY AVAILABLE

The credential, Nationally Certified School Psychologist (NCSP), is granted to persons who have successfully met national training standards by:

A. Completion of a sixth year/specialist level program or higher in school psychology, with a 60 graduate semester hour minimum, consisting of coursework, practica, internship, and an appropriate graduate degree from an accredited institution of higher education.

B. Successful completion of a 1,200 clock hour supervised internship in school psychology, at least one-half of which must be in a school setting.

C. Achieving a passing score on the National School Psychology Examination administered by the Educational Testing Service (ETS).

Persons who hold the credential Nationally Certified School Psychologist (NCSP) meet the criteria for an initial state credential. For renewal, all persons holding the NCSP must complete at least 75 contact hours of continuing professional development activities within a three year period.

6. Credential Renewal/Continuing Education

6.1 State Credential

The credential shall be issued for a period of three years. *Initial renewal* of the state credential shall be contingent upon the applicant providing verified evidence of one year of supervision as described in Standard 5.1 and continuing professional development activities. *Subsequent renewals* shall be granted to applicants meeting the following criteria:

A. Evidence of public, private, or university-based practice for a minimum of one academic year of full-time equivalent (F.T.E.) experience during the previous three years.

B. Evidence of continuing professional development for a minimum of 75 clock hours in the previous three year period during which the credential was in effect.

7. Withdrawal/Termination of the Credential

7.1 The credentialing body has the right to cancel, revoke, suspend, or refuse to renew the credential of any school psychologist, or to reprimand any school psychologist, upon proof that the school psychologist has engaged in unprofessional conduct as defined by NASP's *Principles for Professional Ethics* (1992) or *Standards for the Provision of School Psychological Services* (1992). Such action must be based on a formal finding of guilt by the appropriate adjudicating body after following a documented procedure ensuring that the due process rights of all parties involved have been fully observed.

8. New Application for Credentialing

8.1 All school psychology trainees completing an approved program on or after January 1, 1998 and all other new applicants, shall be trained and credentialed in accordance with these standards. All practitioners currently credentialed shall be recredentialed in an appropriate state or national renewal cycle.

APPENDIX A
Definition of Terms Included in Standards for the Credentialing of School Psychologists

STANDARD 3.2:

NASP *Standards for the Provision of School Psychological Services* (1992): The current standards document from the National Association of School Psychologists (NASP) describing the delivery of appropriate and comprehensive school psychological services for administrative and employing agencies.

Public Setting: Any setting (e.g., school, educational, mental health-related, or university-based) which is legislated, regulated, and/or supported by public funds and whose staff serve, without bias or special selection processes, individuals primarily from the public domain.

Private Setting: Any setting (e.g., school, educational, mental health-related, or university-based) which is supported in whole or in part by private funding sources, which may be for profit, and whose staff can specifically select the populations that it serves.

STANDARD 4.1:

NASP *Standards for Training and Field Placement Programs in School Psychology* (1994): The current standards document from the National Association of School Psychologists (NASP) describing procedural standards supporting the comprehensive training of school psychologists at the doctoral and sixth year/specialist levels.

STANDARD 4.5:

Practica Experiences, as defined in the NASP *Standards for Training and Field Placement Programs in School Psychology* (1994): Practica experiences include orientation to the educational process, assessment for intervention, and direct and indirect intervention methods; are distinct from and occur prior to internship; occur at times appropriate to the specific training objectives of the program; shall be of sufficient length and in settings that are appropriate to specific training objectives of the program; are provided appropriate recognition through the awarding of academic credit; are systematically evaluated in a manner consistent with the specific training objectives of the program; are conducted in accordance with current legal and ethical standards for the profession.

Internship experiences, as defined in the NASP *Standards for Training and Field Placement Programs in School Psychology* (1994): A comprehensive internship experience is required for students to demonstrate, under supervision, their ability to integrate knowledge and skills in providing a broad range of outcome-based school psychological services. Internship experiences are provided at or near the end of the formal training period; occur on a full-time basis over a period of one academic year, or on a half-time basis over a period of two consecutive academic years; are designed according to a written plan that provides a broad range of experiences; occurs in a setting appropriate to the specific training objectives of the program; are provided appropriate recognition through the awarding of academic credit; occur under conditions of appropriate supervision; are systematically evaluated in a manner consistent with the specific training objectives of the program; are conducted in accordance with current legal and ethical standards for the profession.

School Setting (from Appendix B of the NASP *Standards for Training and Field Placement Programs in School Psychology,* 1994): Has the availability of (a) children of all school ages, (b) pupil personnel services functioning within a team framework, (c) regular and special education services at the preschool, elementary, and secondary levels, (d) full-range of services for children with high incidence and low incidence disabilities, (e) at least one credentialed school psychologist having a minimum of three years of full-time school psychology experience, or the equivalent who serves as internship supervisor. It is not essential that the above all be provided within the context of the local educational agency to which the intern is assigned. However, it is essential that all elements be available and integrated into the internship experience.

STANDARD 5:

Approved Programs in School Psychology: The National Association of School Psychologists (NASP) publishes annually a list of training programs in school psychology that have been determined to meet NASP *Standards for Training and Field Placement Programs in School Psychology* (1994). A copy of the Approved Program list can be obtained by contacting the office of the National Association of School Psychologists, 8455 Colesville Road, Suite 1000, Silver Spring, Maryland 20910.

Mentoring and Continuing Professional Development: In addition to the one year of post-degree supervision described in Standard 5.1, it is recommended that individuals enter an organized program of mentoring and continuing professional development. This recommendation is made in recognition of the complex problems in today's schools and the need to continue, enhance, and upgrade school psychologists' professional training and skills in an effort to ensure quality service delivery. Mentoring should be provided by a school psychologist with at least three years experience, and should involve, as is needed, elements of supervision, collegial discussion, and support regarding professional issues. Mentoring is often one component of a continuing professional development plan, and should be arranged in an organized manner to enhance and develop an individual's professional skills and knowledge. Continuing professional development and mentoring may include, but are not limited to, discussions of professional issues with colleagues, readings of professional journals and books, memberships in professional organizations, and participation in formal continuing professional development programs.

STANDARD 7.1:

NASP *Principles for Professional Ethics* (1992): The current document of principles from the National Association of School Psychologists (NASP) describing guidelines for ethical behavior including professional competency, professional relationships and responsibilities, and professional practices in public and private settings.

Appendix V

NASP Continuing Professional Development Program

1.0 PHILOSOPHY AND INTENT

With the inception of the National Certification System for School Psychologists, NASP has, for the first time, a mechanism for advocating its long established position regarding appropriate standards for the provision of school psychological services as it pertains to Continuing Professional Development:

> The practice of school psychology has and will continue to undergo significant changes as new knowledge and technological advances are introduced. The development of new intervention techniques, assessment procedures, computerized assistance, and so forth, will require that practitioners keep abreast of these innovations as well as obtain appropriate professional education and training in these areas. **All school psychologists actively participate and engage in activities designed to continue, enhance, and upgrade their professional training and skills and to help ensure quality service provision** [emphasis added]. These efforts are documented by participation in NASP or other formal Continuing Professional Development (CPD) programs, although they are not limited to such activities. Membership in professional organizations, reading of professional journals and books, discussions of professional issues with colleagues, and so forth, are also an integral component of a school psychologist's overall CPD activities. ["Standards for the Provision of School Psychological Services," *Professional Conduct Manual*, NASP, 1984, Section 4.6]

It is assumed that all school psychologists, and particularly those participating in the National School Psychology Certification System, have a common ethic and goal to grow professionally by keeping abreast of trends and new research in order to enhance their services. Because the knowledge base of the field is broad, training and skill levels are varied, and the professional role has many dimensions, individuals will want to have a personal plan for professional development. The plan should be designed to include a broad range of experiences and should be unique to the needs of the individual. Meeting the requirements of the NASP CPD program (which is part of the National School Psychology Certification System) provides an opportunity to reach this goal.

Inasmuch as school psychologists function in a variety of job assignments in a number of diverse locations, it is important to recognize the variables in availability of formal and informal inservice opportunities. **The intent of the CPD requirement, therefore, is not to limit the school psychologist's continuing professional development by approving only specific activities, but rather to acknowledge and encourage participation in the variety of activities that are available to each individual.**

2.0 PROCESS

Consistent with the *NASP Standards for the Provision of School Psychological Services* (1984), participation in activities designed to maintain and expand skills and to insure quality service provision is the continuing obligation of school psychologists. For renewal of national certification, it is expected that school psychologists will enhance their skills in the following areas as defined in the *Standards* (see Appendix A):

CONSULTATION
PSYCHOLOGICAL AND PSYCHOEDUCATIONAL ASSESSMENT
INTERVENTION
SUPERVISION
RESEARCH
PROGRAM PLANNING AND EVALUATION

The emphasis of CPD is upon recency and regularity of participation in skill development activities. It is also expected that the effective practice of school psychology reflects, at its most basic level, a broad knowledge base, and that, for continued effective delivery, school psychologists enhance their skills in a variety of areas.

2.1 Professional Development Activities

2.1.1 CPD Activities include (see Appendix B for specific explanations):

- 2.1.3.1 National , state and local school psychology association conferences, workshops, and inservice training
- 2.1.3.2 Related professional conferences, workshops, and inservice training
- 2.1.3.3 Completion of college and university courses beyond those required for entry-level certification as a school psychologist
- 2.1.3.4 Teaching courses and provision of workshops and inservice training when not an ordinary aspect of employment
- 2.1.3.5 Research
- 2.1.3.6 Publication
- 2.1.3.7 Presentations
- 2.1.3.8 Intern Supervision
- 2.1.3.9 Post-graduate supervised experiences, when not an ordinary aspect of employment
- 2.1.3.10 Program planning/evaluation when not an employment requirement
- 2.1.3.11 Sequenced programs of self-study
- 2.1.3.12 Informal programs of self-study
- 2.1.3.13 Professional organization leadership

2.1.2 Activities should be chosen as part of an overall professional development plan devised by the participant to enhance knowledge in several foundation areas. While submission of a formal plan is not required, participants are encouraged to devise such a plan for their own use.

2.1.3 Participation time must be accrued **in at least three of the six specific skill areas** (see Section 2.0).

2.1.4 The individual will participate in a variety of activities which emphasize learning, including coursework or workshop experiences and instruction, presentations, program development, or research. These activities go beyond the ordinary aspects of employment.

2.2 CPD Credits

2.2.1 Maintenance of National School Psychology Certification requires the completion of **75 CPD credits,** or 75 contact hours or their equivalency of professional development activity.

2.2.2 A contact hour is defined as an actual clock hour (60 minutes) spent in direct participation in a structured educational format as a learner.

2.2.3 When college or university courses are taken to fulfill the CPD requirement, the following equivalencies shall be used: 1 semester hour = 15 CPD credits; 1 quarter hour = 10 CPD credits.

2.2.4 Some organizations may represent CPD activities through the use of Continuing Education Units (CEUs). One CEU is typically equivalent to *10 contact hours.*

2.2.5 When CPD activities cannot be represented by contact hours, CPD credit equivalencies and ceiling limits have been established (see Appendix B).

2.2.6 For purposes of Nationally Certified School Psychologists (NCSP) renewal, all activities should be reported in terms of CPD credits.

2.3 Claiming CPD Credit for Activities

2.3.1 Individuals may claim CPD credits for a variety of activities. The activities may be evaluated and selected by the individual, as described in 2.3.2.

2.3.2 Individuals may evaluate and select CPD activities and may claim the activities for CPD credit *without contacting NASP for pre-approval of these activities.* The following steps should be used:

2.3.2.1 Evaluate an activity to determine if it may be claimed for CPD credit. Only activities for which each of the following questions can be answered with a "yes" by the individual may be claimed for CPD credit.

- Did the activity enhance or add to my knowledge base?
- Was the activity relevant to the professional practice of school psychology?
- Did the activity fit into my personal plan for continuing professional development?
- Did the activity go beyond the ordinary aspects of my employment?

2.3.2.2 Determine the activity category for the activity by referring to the descriptions in Appendix B. If the activity does not fall into an activity category, do not claim the activity for CPD credits.

2.3.2.3 Determine the skill area for the activity by referring to the descriptions in Appendix A and selecting the skill area(s) that was most enhanced or upgraded by the activity.

2.3.2.4 Determine the number of CPD credits to claim for the activity by referring to the CPD credit equivalencies and credit ceilings in Appendix B.

2.3.2.5 Verify the activity with the required documentation listed in 3.1 and Appendix B.

2.3.2.6 File the verification of the activity to submit with other materials at the time of NCSP renewal.

3.0 PROCEDURES

3.1 Documentation

3.1.1 Participation in CPD activities must be documented.

3.1.2 For purposes of NCSP renewal, the NASP CPD Summary Sheet (see Appendix C) must be completed and all CPD activities and credits must be listed on the Summary Sheet.

3.1.3 Verification of participation for each activity listed must be submitted with the NASP CPD Summary Sheet(s). Several forms of verification will be acceptable (see Appendix B).

3.1.3.1 Certificates or log sheets of participation provided by the CPD sponsor may be submitted as verification.

3.1.3.2 When CPD involves college or university coursework, a copy of the course transcript will serve as verification.

3.1.3.3 In states where professional development is required for maintenance of certification or licensure, or in school districts or other agencies and organizations where professional development is required, summary reports or activity validation forms generated by the state board of education, credentialing agency, school district, or other agency or organization may be submitted as verification of participation.

3.1.3.4 Any activity not otherwise documented per the above instructions is to be documented through completion of an Activity Documentation Form (see Appendix D). A separate Activity Documentation Form is to be submitted for each activity claimed.

3.1.4 If an individual participates in a state or local school psychology association's CPD program *that has been pre-approved by NASP,* the individual may submit a state or local association's CPD summary report(s) for NCSP renewal instead of NASP's CPD Summary Sheet and verification of each individual activity. A list of CPD programs that have been pre-approved by NASP is available from the NASP National Headquarters.

3.2 Submission of Documentation for National Certification Renewal

If CPD activities are used to renew status as an NCSP, the following procedures must be followed:

3.2.1 NCSP renewal occurs on a three year cycle. CPD credit must be accrued within the three year cycle prior to renewal.

3.2.2 Prior to each third anniversary of the individual's national certification, the National School Psychology Certification Board (NSPCB) will notify the participant of renewal procedures.

3.2.3 Documentation of CPD activities will be submitted as part of the renewal procedure.

3.2.4 Documentation to be submitted will include the NASP CPD Summary Sheet, verification of participation for each activity listed on the CPD Summary Sheet, the NCSP renewal questionnaire, the Directory Listing and the appropriate renewal fee.

3.2.5 Questions regarding the acceptability of a specific activity should be directed to the NASP Professional Development Committee prior to application for renewal.

3.2.6 The documentation submitted for NCSP renewal will be reviewed and approved according to procedures established by the Professional Development Committee.

3.2.7 Documentation will not be returned to the NCSP. Therefore, copies, rather than original documents, are acceptable.

APPENDIX A
Continuing Professional Development Skill Area Definitions

The areas of skill development cited in Section 2.0 of the NASP Continuing Professional Development Program document are those defined in the NASP *Standards for the Provision of School Psychological Services* (1984) Section 4.3. The salient points of that section of the document are reprinted here to assist the participant in determining the skill area(s) under which a specific CPD activity might fall.

CONSULTATION

1. Activities which enhance the school psychologist's skill in:
   a. mental health consultation
   b. behavioral consultation
   c. educational consultation with parents, school personnel, or outside agencies.
2. Training in the promotion of:
   a. mental health and learning
   b. prevention of disorders
   c. improving educational systems
3. Provision of inservice in the areas of:
   a. human learning
   b. human development
   c. behavior to parents, school personnel, and others in the community
4. Development of skills to enhance collaborative relationships with clients, including:
   a. students
   b. school personnel
   c. parents
   d. outside agencies

PSYCHOLOGICAL AND PSYCHOEDUCATIONAL ASSESSMENT

1. Development of skills in multifactored assessment
2. Enhancement of skills in specific assessment areas, including:
   a. personal-social adjustment
   b. intelligence
   c. scholastic aptitude
   d. adaptive behavior
   e. language and communication skills
   f. academic achievement
   g. sensory and perceptual motor functioning
   h. environmental-cultural influences
   i. vocational development, aptitude and interests
3. Development of skills in non-test based measurement, including:
   a. observation
   b. behavioral measurement
4. Development of skill in non-biased assessment
5. Activities that promote ethical considerations and conduct regarding evaluation of students

INTERVENTION

1. Skill development in both direct and indirect intervention strategies that will enhance or facilitate the functioning of:
   a. individuals
   b. groups
   c. systems
2. Enhancement of theory and practice in designing programs to enhance:
   a. cognitive development
   b. affective development
   c. social development
   d. vocational development
3. Assisting others within the community to enhance service delivery skills through such avenues as:
   a. inservice
   b. organizational development
   c. parent counseling
   d. parent education

SUPERVISION

1. Participation in specific activities which enhance the school psychologist's supervisory and administrative skills
2. Provision of practicum and/or internship experiences to school psychology graduate students

RESEARCH

1. Designing or conducting research of a psychological and educational nature, including:
   a. psychological functioning of human beings
   b. psychoeducational assessment tools and procedures
   c. educational programs and techniques applied to individual cases and groups of various sizes
   d. educational processes
   e. social system interactions and organizational factors associated with school communities
   f. psychological treatments and techniques applied to individual cases or groups

PROGRAM PLANNING AND EVALUATION

1. Development of skills in the area of program planning and evaluation
2. Provision of program planning and evaluation services that assist in decision-making
3. Serving on committees responsible for developing and planning educational and educationally-related activities

APPENDIX B

CPD Credit Equivalencies and Credit Ceilings

The NASP Continuing Professional Development Program lists a variety of activities which have potential for enhancing a school psychologist's knowledge and the quality of service provision. These activities are listed in the *CPD Program* document in Section 2.1.1 CPD credit equivalencies and credit ceilings for activities are described in the following sections of Appendix B.

Group A: Hour-for-Hour Activities:

All workshop, conference, and inservice training activities earn one hour of CPD credit for each contact hour of participation:

2.1.3.1 National, state, and local school psychology association conferences, workshops, and inservice training

2.1.3.2 Related professional conferences, workshops, and inservice training

An Example: Two hours of attendance at a NASP Convention miniskills workshop = 2 contact hours or 2 CPD credits.

Group B: Standard Conversions:

Taking or teaching college/university courses and provision of workshops and inservice training are credited on a standard basis as follows:

2.1.3.3 Completion of college courses and university courses beyond those required for entry level certification

a. The participant earns 10 CPD credits for each hour of course credit if the course is for *one quarter*

An Example: A 3-quarter credit course in consultation earns 30 CPD credits

b. If the course is for *one semester*, then one hour of course credit is worth 15 CPD credits

An Example: A course in advanced research earns 3-semester hours = 45 CPD credits

2.1.3.4 Teaching courses and provision of workshops and inservice training when not an ordinary aspect of employment

CPD credit should not be claimed for activities which are a part of the school psychologist's regular job requirements. However, credit may be claimed for those teaching/presenting activities which go beyond the normal demands of that psychologist's job setting. Additionally, although the course or inservice training may be reported, credit may only be claimed once. Credit claimed is equal to the number of contact hours obtained by those attending the course or workshop, as described in items 1–3 above.

Examples: A university trainer presents a workshop on curriculum-based assessment at a state conference. The workshop is 4 hours long. Participants obtain 4 CPD hours of credit. The presenter may also claim 4 CPD credits. However, credit may only be claimed *once* for workshops on this subject.

A school psychologist teaches one course as a guest lecturer at a local university. Students taking the course earn 3 semester hour credits. The lecturer can earn 45 CPD credits for teaching the course. However, the school psychologist may only obtain those credits the *first* time the course is taught.

Group C: Conversions and Limitations:

Other types of activities are also valuable in professional development. However, participation in these activities is *not covered on a per hour basis alone*. These activities might:

1. require more actual time than the credit that may be earned
2. be limited in the credit they offer

Limited activities include the following:

2.1.3.5 Research

2.1.3.6 Publication

2.1.3.7 Presentation

To claim credit in these categories, it is necessary for the participant to reasonably estimate the amount of time spent and claim those actual hours up to the maximum specified. Also, the participant should claim credit *only once for any project.*

- Unpublished Research — up to 10 CPD credits
- Research *and* publication or presentation on a topic — up to 25 CPD credits
- Non-research based published articles with references *or* poster presentation at a state or national convention — up to 10 CPD credits
- Published theoretical or editorial articles — up to 5 CPD credits

2.1.3.8 Supervision of interns in field placements by school psychologists.

For purposes of claiming CPD credits, field supervisors should consider the extent to which this role leads to professional growth on the part of the supervisor. Up to 10 CPD credits may be obtained for supervising one or two interns for one academic year. Credit for supervision may be claimed *no more than twice* (two years) during a three-year renewal period.

An Example: A school psychologist supervised an intern for 1 academic year. They decided to lead a group at one of the elementary schools for children whose parents were divorced. This and several other activities involved new learning for both the supervisor and intern. The supervisor may claim 10 CPD credits.

2.1.3.9 Post-graduate supervised experiences when not an ordinary aspect of employment, including post-graduate fellowships, internships, or supervised work experiences.

Following completion of their school psychology degrees, many school psychologists participate in supervised fellowships, internships, or other experiences in order to acquire new knowledge and skills. The supervised experiences may occur in settings outside the school psychologist's regular job setting or may occur as part of a planned and sequential program on the job. For purposes of claiming CPD credit for this activity category, school psychologists should consider the extent to which the supervised experience leads to professional growth and new knowledge and skills. CPD credit may *not* be claimed for regular supervised experiences that are required as part of the school psychologist's typical employment. CPD credit may be claimed according to the percentage of the school psychologist's time spent in the supervised experience, according to the following:

Quarter time for one academic year — 5 CPD credits

Half time for one academic year — 10 CPD credits

Three-quarters time for one academic year — 15 CPD credits

Full time for one academic year — 20 CPD credits

Credit for supervised experiences may be claimed *no more than twice* (two years) during a three year renewal period. *Note:* If the experience is taken for university/college course credit, activity category 2.1.3.3 should be used instead of activity category 2.1.3.9. In addition, some activities during the supervised experience, such as attendance at conferences or inservice training or informal programs of self-study may earn CPD credits in other activity categories listed in Appendix B.

Examples: A school psychologist wishes to enhance her skills in family counseling and intervention. She makes arrangements with her school district to spend 25% of her time for one academic year to receive training and experience in this area, under the supervision of a qualified school psychologist in another school. She may claim 5 CPD credits for this activity.

A school psychologist takes a one academic year leave of absence from her job to participate in a full-time, supervised fellowship program at a children's hospital. She may claim 20 CPD credits for this activity.

2.1.3.10 Program planning/evaluation, when not an ordinary aspect of employment

As with the research/publication categories above, actual hours should be claimed, but *no more than* 25 CPD credits for one project may be obtained in this area, and no more than one project may be claimed in a three year period.

An Example: A school psychologist promotes the development of teacher assistance teams in the district. Considerable time is spent planning for the program, training staff, developing procedures, etc. The psychologist estimates 80 actual hours of work. A total of 25 CPD credits are claimed.

2.1.3.11 Sequenced programs of self-study

Programs developed and published to provide training in a specific knowledge or skill area are valued for obtaining CPD credits. *No more than two topics may earn credit in this category during a three-year renewal period.* Credit may be determined by:

- obtaining the CPD designated by program developers.

  An Example: A course on non-biased assessment is developed by NASP for Continuing Professional Development. It involves purchasing a course manual and video tapes. The credit offered is 20 CPD credits.

- estimation of credit based on time spent mastering the material. Credit obtained in this manner is limited to 15 CPD credits.

  An Example: A course on Counseling Techniques with Children involved 20 hours of reading, 3 hours of audio tapes, and 3 written exercises. A total of 15 CPD credits may be claimed.

2.1.3.12 Informal programs of self-study

When a school psychologist pursues a topic of interest by systematically reviewing the literature, developing a comprehensive list of resources and studying these resources, CPD credits may be obtained. Included in this category would be book, journal, and manual reading. To obtain credit, the psychologist must provide the reading list with the Activity Documentation Form (see Appendix D). At least 4 resources should be included on any one topic. Actual hours claimed in this activity are not to exceed 15 CPD hours per topic. *No more than two topics may earn credit in this category during a three-year renewal period.*

An Example: A school psychologist decides to study "collaborative consultation." A review of the literature reveals 5 well-known authors on this topic. Additionally, the *School Psychology Review* lists four recent articles. The psychologist spends 20 hours reading these and earns 15 hours of CPD credit.

2.1.3.13 Professional organization leadership

A school psychologist who holds a position in a local, state, or national professional organization may earn:

- 10 CPD credits as president
- 5 CPD credits as other officer
- 5 CPD credits as committee chair, delegate, or regional director

Credit may be obtained for no more than *one position, per year, per organization.* No more than 20 CPD credits may be obtained in this category during a three-year renewal period.

An Example: A school psychologist serves as treasurer of the state school psychology association one year and holds a NASP delegate position for all three years of a renewal period. She may claim 5 credits for the treasurer's position and 15 hours for the delegate's position (5 CPD credits for each of three years) for a total of 20 hours. This activity should be claimed under the area of Program Planning and Evaluation.

CPD CREDIT EQUIVALENCIES AND CREDIT CEILINGS SUMMARY TABLE

ACTIVITY CATEGORY	CPD CREDIT CONVERSION	CEILING LIMITS	DOCUMENTATION REQUIRED
2.1.3.1 School psychology workshops/conferences/ inservice training	Each hour = 1 CPD	None	Certificate of Attendance or Activity Documentation Form and receipt
2.1.3.2 Other professional workshops/conferences/ inservice training	Each hour = 1 CPD	None	Certificate of Attendance or Activity Documentation Form and receipt
2.1.3.3 College/university courses	One quarter hour = 10 CPD One semester hour = 15 CPD	None	Transcript
2.1.3.4 Teaching/workshop and inservice presentation	Hour-for-hour or university credits as defined in 2.1.3.1-3 above	Credit may be claimed only first time content is taught.	Copy of syllabus for course or copy of program flyer or Activity Documentation Form
2.1.3.5 Research 2.1.3.6 Publication 2.1.3.7 Presentations	Actual hours, up to ceilings established	Unpublished research=10 CPD. Research & publication or presentation=25 CPD. Article published or poster presented = 10 CPD. Theoretical/ editorial article = 5 CPD. Each project may only be claimed once.	Activity Documentation Form and Abstract of Program, if possible
2.1.3.8 Intern supervision	1 year of supervision = 10 CPD	Only one intern claimed per year. No more than 2 interns in 3 years.	Activity Documentation Form
2.1.3.9 Post-graduate supervised experiences	1/4 time = 5 CPD 1/2 time = 10 CPD 3/4 time = 15 CPD full time = 20 CPD	No more than 2 supervised experiences in 3 years	Activity Documentation Form
2.1.3.10 Program planning/evaluation	Actual hours, up to ceiling	1 project = 25 CPD	Activity Documentation Form
2.1.3.11 Sequenced self-study	Actual hours, up to ceiling	1 project = 15 CPD (or other as established). No more than 2 topics in 3 years.	Activity Documentation Form
2.1.3.12 Informal self-study	Actual hours, up to ceiling	1 topic = 15 CPD. No more than 2 topics in 3 years.	Activity Documentation Form
2.1.3.13 Professional organization leadership	President = 10 CPD Other officer = 5 CPD Committee Chair/ delegate/regional director = 5 CPD	No more than one activity per organization per year. No more than 20 CPD in this category in 3 years.	Activity Documentation Form

I certify that this activity merits CPD credit in that it meets the following criteria:

1. This activity enhanced or upgraded my professional skills or added to my knowledge base.
2. This activity was relevant to the professional practice of school psychology.
3. This activity fits into my personal plan for continuing professional development.
4. This activity went beyond the ordinary aspects of my employment.

NASP Position Statements

Ability Grouping

To ensure educational equity and excellence for all America's youth. NASP supports the creation of inclusive classrooms that are based on the belief that all students can learn — a core value of all schools in a democracy. NASP believes that tracking, or whole class ability grouping, is not consistent with that core value.

Extensive research on ability grouping has documented the following negative effects:

- Students with lower ability achieve less in lower track classes than in mixed ability classes.
- Students with higher ability do not achieve more in tracked classes than in mixed ability classes.
- Placing students with lower ability in tracked classrooms reduces self-esteem, with a particularly negative effect on students' sense of their own academic competence.
- Tracking students reduces the likelihood that students placed in lower track classes will choose college preparatory courses.
- Tracking students reduces opportunities to develop relationships among students from other racial, ethnic, and socioeconomic groups and has a negative effect on race relations.
- The placement decision concerning ability grouping is often made very early in a student's school career, is often based on questionable data, and is enduring.

NASP believes that grouping students heterogeneously offers advantages unavailable in schools that track. When implemented appropriately, heterogeneous grouping:

- gives all students equal access to an enriched curriculum and the highest quality instruction schools have to offer;
- avoids labeling and stigmatizing students with lower ability;
- promotes higher expectations for student achievement;
- reduces in-school segregation based on socioeconomic status, race, gender or ethnicity, or disability;
- encourages teachers to accommodate individual differences in students' instructional and social needs;
- enables students to learn from their peers, including students whose background may be very different from their own; and
- emphasizes effort more than ability.

NASP recognizes that heterogeneous grouping will not automatically guarantee all students a quality education. "Watering down" the curriculum or "teaching to the middle" will create disadvantages for able students and should be avoided. While NASP believes that all students can benefit from a more challenging curriculum, we also strongly support the development of a curriculum which recognizes and accommodates individual differences in learning styles, abilities, and interests. To be successful, mixed ability grouping must occur within the context of such a curriculum.

NASP also recognizes that heterogeneous classes require instructional and organizational innovations to accommodate a wide range of learners. Such approaches include cooperative learning groups, peer tutors, flexible grouping practices, team teaching, multi-age groupings, and instruction in higher order thinking and problem-solving skills. Where teachers do not currently possess competencies to enable them to work effectively with mixed ability classes, a commitment to further training is essential.

NASP believes that "untracking" schools requires careful planning and collaboration among constituent groups, including teachers, administrators, support personnel, students, and parents. Planned change can best take place using a model that includes the following:

- a steering committee composed of educators, parents, community members and school board representatives whose task is to study grouping practices and make policy recommendations to the school board;
- local self-study to assess the impact of grouping practices within the school community;
- wide dissemination of local and national studies of ability grouping effects;
- implementation of a strategic plan that allows for a phase-in process and ensures monitoring troubleshooting, and evaluation.

NASP believes that school psychologists can play a central role in helping schools develop appropriate alternatives to tracking. School psychologists have access to research, understand good instructional practices that enhance learning for all students, and possess group problem-solving skills that make them valuable as members of steering committees and strategic planning groups and as staff trainers.

School psychologists can contribute to the process of untracking schools by:

- making research available to administrators and central office personnel;
- leading informal study groups to explore alternative grouping practices;
- becoming members of steering committees assembled to study tracking and to develop policy recommendations; and
- participating in strategic planning and staff development to prepare for untracking.

NASP recognizes that schools cannot simply eliminate tracking but must develop viable alternatives. Developing alternatives to tracking will take patience and careful planning. In order for schools to live up to the promise of educating all students to become productive citizens of the 21st century, NASP believes these alternatives must be characterized by fairness and challenge, with equity and excellence equally available to all learners.

Adopted by the NASP Delegate Assembly, April 17, 1993.

This position statement drew on material from George P. (1992). Alexandria, VA: Association for Supervision and Curriculum Development.

Goals 2000

The National Association of School Psychologists (NASP) strongly supports the creation of national education goals. Goals 2000 sets forth eight National Education Goals:

1. All children in America will start school ready to learn.

2. The high school graduation rate will increase to at least 90 percent.

3. American students will leave grades four, eight, and twelve having demonstrated competency in challenging subject matter, including English, mathematics, science, history, and geography, and every school in America will ensure that all students learn to use their minds well, so they may be prepared for responsible citizenship, further learning, and productive employment in our modern economy.

4. The Nation's teaching force will have access to programs for the continued improvement of their professional skills and the opportunity to acquire the knowledge and skills needed to instruct and prepare all American students for the next century.

5. United States students will be first in the world in science and mathematics achievement.

6. Every adult American will be literate and will possess the knowledge and skills necessary to compete in a global economy and exercise the rights and responsibilities of citizenship.

7. Every school in the United States will be free of drugs, violence, and unauthorized presence of firearms and alcohol and will offer a disciplined environment conducive to learning.

8. Every school will promote partnerships that will increase parental involvement and participation in promoting the social, emotional, and academic growth of children.

The broad purposes outlined in these eight National Education Goals and the nine year strategy to achieve these goals are important steps in committing the United States to develop a world class education system.

To achieve these goals the focus of education must extend beyond academic goals alone. The impact of social-emotional, health, and mental needs of children and youth on school achievement must be addressed if the desired outcomes are to be achieved. Students who are not motivated to learn, who are abused or neglected, who come from backgrounds in which education is not a priority, who are part of highly mobile families, or who are otherwise at risk are not in a position to achieve these goals without the proper levels of support. History has shown us that each time academic standards are raised in this country, at-risk student groups are further alienated unless specific strategies are developed to prevent their disenfranchisements. Pupil services personnel, including school psychologists, are in the best position to identify and respond to those concerns and to facilitate the attainment of these goals by all children and youth.

The NASP position statement, "At Risk Students and Excellence in Education: The Need for Educational Restructuring," sets forth the view that minor adjustments to the current educational system is no longer a credible solution. As an example, increased academic time is essential but simply adding more hours, standards, and requirements will not meet the goals of either equity or excellence.

To arrive at effective solutions to address the weaknesses of our educational system, the National Educational goals must incorporate the following values and guiding principles:

- **Provide high quality education for *all* children.** To do this we must take into account the special needs of students with disabilities, students at risk for school failure, children and youth of poverty, children and youth of diverse backgrounds, and students with gifts and talents.

- **Provide community and family support for educational readiness.** All children must be given a legitimate opportunity to learn. Reaching the National Educational Goals requires competent and committed parents, wanted and healthy children, adequate nutrition, appropriate nurturing, decent housing, and freedom from abuse, neglect, and exploitation. Children must be provided with environments that encourage their eager participation, exploration, and curiosity about the world.

- **Address the diverse needs of students.** Academic success, the social and emotional, developmental and family needs of all students must be addressed. Academic gains will be made only after these other "basic" needs of students have been met. Education in the 21st century must expand its "curriculum" to include these needs.

- **Support intervention and prevention programs.** Prevention and early identification of problems combined with immediate intervention are the most effective methods to make school a success for all children and youth. Such programs are essential for the success of the National Education Goals.

- **Emphasize the parental role in children's school success.** Home–school collaboration goes hand-in-hand with efforts to redesign education for children and youth. These family-oriented efforts will promote the critical linkages between school and home in the areas of effective parenting, methods of working and communicating with children, inclusion of students with disabilities, and ensuring effective home-communication with schools.

- **Promote alternatives to corporal punishment.** If schools are truly to be "safe havens" for learning and growing for all students, corporal punishment must be abolished. Students must be safe from physical harm from those adults who are entrusted with their care. Teachers can be prepared to use positive alternatives to corporal punishment that are more effective in establishing appropriate classroom discipline and promoting academic achievement.

School psychologists are essential personnel in the schools. Their presence will directly facilitate the attainment of education goals by all students. To help reach the National Education Goals, school psychologists can:

- Design, implement and evaluate prevention and early intervention programs.
- Address a wide range of behavioral problems through the implementation of programs such as substance abuse prevention, violence reduction, social skills training, crisis intervention, schoolwide effective discipline programs, etc.
- Work with parents by providing parents education and facilitating home–school collaboration.
- Provide information on how individual differences affect school achievement and have knowledge of instructional methods to address diversity in the classroom and to promote critical thinking and problem-solving in all students.
- Provide collaborative professional development to enable an increasingly diverse student population to utilize their strengths and learning skills.
- Assist in classroom management and behavior management essential for increasing academic engaged time and enhancing effective classroom instruction.
- Provide information about the factors that place students at risk for school failure and have the skills to implement programs to prevent school failure and reduce school dropout.
- Help school personnel understand the developmental education needs of children and youth; and
- Develop a collaborative support system so that teachers and other instructional staff are able to teach to the "fullest."

No important social aims are ever achieved by rhetoric. The strategies to restructure American education must be predicated on strong and continuing federal leadership, investment in human and related capital, and collaboration among families, service providers, government, and the private sector. Coordination of the separate efforts of the individual states, localities, and the private sector is essential if the National Educational Goals are to be achieved in a way that promotes and ensures excellence and equality.

The National Association of School Psychologists believes that the federal government must provide adequate financial support to ensure the achievement of the National Education Goals. States and localities throughout the country are experiencing unprecedented fiscal crises of such proportion that education budgets are being severely slashed. These realities profoundly affect the ability to plan and implement change. Even under the optimal financial circumstances, states and localities are likely to devote differing amounts of resources to restructuring education. The values exemplified in Goals 2000 must be matched with a willingness to invest the fiscal resources of the United States to make achievement of the National Goals a reality.

Adopted by the NASP Delegate Assembly, March 1992.

Advocacy for Appropriate Educational Services for All Children

PL 94-142 (The Education of All Handicapped Children Act) has achieved major goals in serving handicapped children, many of whom had been previously excluded from appropriate educational programs. Since its enactment in 1975, all handicapped children have been guaranteed a free and appropriate education, the right to due process, and individualization of program according to need. We strongly support the continuation of legislation which has mandated these guarantees.

We also recognize that serious problems have been encountered as school districts strive to meet these mandates and that quality education is still an elusive goal. some of these problems reflect difficulties within special education; others appear to be special education issues but have their origins in the regular education system.

One major set of problems involves reverse sides of the issue of access to appropriate education: (1) On the one hand, access to special eduction must be assured for all significantly handicapped children who need and can benefit from it. (2) Conversely, children are being inappropriately diagnosed as handicapped and placed in special education because of: (a) a lack of regular education options designed to meet the needs of children with diverse learning styles; (b) a lack of understanding, at times, of diverse cultural and linguistic backgrounds; and (c) inadequate measurement technologies which focus on labels for placement rather than providing information for program development.

It is not a benign action to label as "handicapped" children who are low achievers but are not, in fact, handicapped, even when this is done in order to provide them with services unavailable in general education. Special personnel often resort to labeling because it seems the only way to obtain needed services for children. This is an unfortunate result of categorical models which attach funding to classifications. Other problems originating in the classification system include:

- Labels that are often irrelevant to instructional needs.
- Categories, based on deficit labels, that are rather arbitrarily defined, particularly for mildly handicapped and low achieving students, but which seem to be accepted as "real" and may prevent more meaningful understanding of the child's psychoeducational needs. The intent of this statement is not necessarily to endorse mixing children with different moderate to severe handicaps in a single special education classroom.
- Reduced expectations for children who are placed in special needs programs.
- Assessment processes aimed at determining eligibility which often deflects limited resources from the determination of functional educational needs and the development of effective psychoeducational programs.
- A decreased willingness on the part of regular education, at times bordering on abdication of responsibility to modify curricula and programs in order to better meet the diverse needs of all children.

As increasing numbers of children are classified as handicapped and removed from regular classrooms for special instruction, there has been a dramatic reduction in the range of abilities among children who remain within the general education system. Concurrently, as national standards for excellence are being raised, the number of children at risk for school failure is growing dramatically. Without provisions to prepare students for higher expectations through effective instructional programs, many of these children may also be identified as handicapped and placed in special education. This climate, in which children are tested and labeled as failures or as handicapped in increasing numbers, creates an urgent need for reexamination and change in the system which provides access to services.

In view of these problems, and based upon the commitment to see that all children receive effective and appropriate education irrespective of race, cultural backgrounds, linguistic background, socioeconomic status, or educational need, we believe:

- All children can learn. Schools have a responsibility to teach them, and school personnel and parents should work together to assure every child a free and appropriate education in a positive social environment.
- Instructional options, based on the individual psychoeducational needs of each child, must be maximized within the general education system. Necessary support services should be provided within general education, eliminating the need to classify children as handicapped in order to receive these services.
- Psychoeducational needs of children should be determined through a multi-dimensional, non-biased assessment process. This must evaluate the match between the learner and his or her educational environment, assessing the compatibility of curriculum and system as they interact with the child, rather than relying on the deficit based model

which places the blame for failure within the child. Referral to the assessment and placement process must always relate directly to services designed to meet psychoeducational needs.

- In addition to maintaining current protection for handicapped children, protections and safeguards must be developed to assure the rights of children who are at risk for school failure and require services while remaining in general education without classification as handicapped.

We propose a new national initiative to meet the educational needs of all children:

We propose the development and piloting of alternatives to the current categorical system. This requires reevaluation of funding mechanisms, and advocacy for policy and funding waivers needed for the piloting of alternative service delivery models. It also requires the development of increased support systems and extensive retraining of all school personnel to enable them to work effectively with a broad range of children with special needs within the regular education system.

This initiative will encourage greater independence for children by enabling them to function within the broadest possible environment, and independence for school personnel by providing them with training and support so they can help a wide range of children.

The types and extent of change we are suggesting should be made cautiously. Targeted funds intended for children with moderate and severe handicapping conditions must be protected. Similarly, resources for children who are not handicapped, but who experience learning difficulties, must be protected even though these children are served within general education. We need to assure that no child is put at risk for loss of services while the change process is occurring.

Our task is to reduce the rigidities of the current system without taking away the protections offered by PL 94-142. All experimentation and research must take place within a framework of maximum protection for children. It is highly likely that this may require the development of temporary parallel systems — the traditional system of classification and placement under PL 94-142, and a system of experimental programs, primarily within general education — until satisfactory models can be developed which meet the requirement of accountability, due process, and protection of students' and parents' rights, and provide funding for students in need of services. In addition, while these recommended modifications might reduce the risk of misclassification due to cultural or linguistic differences, we caution that these issues must continue to be monitored and discussed during the transition period and beyond.

Because of the complexity of these issues, the generation of effective solutions will require a national effort of interested persons and organizations which we hope to generate through this task force. We will actively work toward the collaboration of a wide variety of individuals and organizations, joining together to develop a strong base of knowledge, research, and experience in order to establish new frameworks and conceptualizations on which to base decisions, design feasible service delivery options, advocate for policy and funding changes needed to implement these alternatives, and coordinate efforts and share information for positive change. We invite you to join us.

This statement issued jointly by the National Association of School Psychologists and the National Coalition of Students.

AIDS

Acquired Immune Deficiency Syndrome (AIDS) currently threatens the physical and mental health and the civil liberties of many persons in America. Children and youth particularly may be at risk. Many teenagers engage in high-risk activities. Over 70 percent of our teenagers have had sexual intercourse by the age of twenty, many with more than one partner. Nearly one-half of all sexually transmitted disease patients are under 25 years of age. In 1986, approximately 1.1 percent of high school seniors reported having used heroin. Certain populations hold even higher risk; approximately 80 percent are Black and Hispanic.

School systems have a major responsibility both in the acceptance of children who have AIDS and in the education about risk reduction. Because a cure will not be available in the foreseeable future, education about risk reduction is the primary prevention strategy currently available.

Rights to an Education

NASP affirms the right of children who have AIDS to an appropriate education in the least restrictive environment. Toward that end, school psychologists have an active role in working with other educators to sensitize and educate the community, school staff, and students to the needs of these children.

AIDS Education and Related Services

Education currently is the only effective weapon in the battle against AIDS. NASP supports the U.S. Surgeon General C. Everett Koop's recommendations for early and continuing AIDS education in our schools.

Transmission of AIDS information alone will not be adequate to establish and maintain appropriate behaviors that reduce the risk of HIV transmission. Research has shown that educational programs designed to effect behavior change should address the topics of decision making, risk assessment, attitude change, group norms, and other social and psychological processes, as well as factual knowledge.

All responses of the school must be tailored to the individual needs of students. AIDS education must be culturally sensitive, gender-relevant, and appropriate to the level of intellectual, emotional, and social development of the student. AIDS education must be appropriate for handicapped students, students with low literacy levels, and non-English speaking students.

AIDS education should be integrated into dropout prevention, school reentry, and community-based outreach programs.

Developmentally appropriate AIDS education must start as early as the lower elementary grades in order to establish appropriate attitudes and behaviors. AIDS education must be incorporated into a comprehensive health education program that includes sex education, family life education, and drug education. Specific behaviors through which the virus can be transmitted must be addressed.

Related services — including counseling of students and parents about feelings, behaviors, and decision-making — must be available.

School community programs must be developed with the active involvement of parents. Parent education should be provided so that parents can discuss factual information with their children within the context of their own family values.

Staff development for school personnel should be available and should include accurate factual information, as well as helping them deal with their own fears and feelings about AIDS.

Role of the School Psychologist

Because of their training in human development, psychological processes, learning processes, and educational systems, school psychologists can play an important role in the integration of children with AIDS into schools and in the education for risk reduction. School psychologists should be aware that the issue of AIDS education is controversial. NASP encourages all school psychologists to learn the necessary information and to provide their expertise in order to facilitate the provision of effective AIDS education and to provide necessary related services to students with AIDS and/or high risk students.

In collaboration with other support and education personnel, school psychologists can:

- Assist in the development, implementation, and evaluation of AIDS education that is appropriate for age, gender, ability level, and cultural group;
- Facilitate parental involvement in AIDS education in the school, home, and community;
- Participate in the decisions about educational and related services for a child infected with HIV;
- Respond to the educational and psychological needs of students, parents, and school personnel who are concerned about school attendance of a student known to be HIV-infected, at perceived high risk of infection, or who has a family member with HIV infection;
- Provide counseling for students who have a family member or friend with AIDS, students at high risk or perceived high risk of HIV infection, or students with AIDS.

- Help teachers, administrators, and parents recognize and address their general feelings and personal concerns regarding AIDS.
- Work with other support and education personnel to establish and maintain appropriate AIDS-related behaviors and attitudes in students.

Adopted by the NASP Delegate Assembly, April 1988

At-Risk Students and Excellence in Education: The Need for Educational Restructuring

The Imperative for Change

Significant changes in social and economic contexts have rendered traditional school structures ineffective. Numerous reports calling for educational reform have been published in recent years; and educators, citizens, and policy makers alike now recognize the serious problems inherent in our current educational system. Some reports have recommended higher standards and expectations, greater emphasis on basic skills or technological training, and increased accountability. Others have called for more widespread application of effective schools and teaching research.

More recently, concern has focused on the increased numbers of students in our schools at-risk for academic and personal problems. Educators and the community at large acknowledge the devastating economic and social impact of high student dropout rates, students graduating without functional skills, and students experiencing serious academic and personal problems which prevent them from becoming productive members of society. Schools are facing increasing numbers of students with multiple risk factors — children from single parent homes, from immigrant families, from poor families, from dysfunctional families — as well as ethnic minorities who historically have been denied access to the training and employment needed to participate in an increasingly complex society. Social-personal problems confronting students, such as teenage pregnancy, substance abuse, neglect, peer pressures, and family stress, contribute to increasingly complex educational needs.

It has become clear that striving for excellence in education without also ensuring equity leaves large numbers of students disenfranchised. NASP is committed to finding the most effective ways to educate all students. The NASP position statement, Advocacy for Appropriate Education for All Students (1985), recognized the limitation of categorical approaches in meeting the needs of students with learning problems and called for careful piloting of alternative delivery systems that increase access and reduce barriers to effective instruction for all students. We renew and expand this call for alternatives to the current educational delivery system.

NASP believes that many of our basic assumptions about schooling need to be reconsidered. Given the magnitude of the problems, making minor adjustments to the current educational system is no longer a credible solution. While increased academic time is essential, simply adding more hours, more standards, and more requirements will not meet the goals of either equity or excellence.

Among the traditional assumptions that need to be questioned are age-graded, lock-step classes, extensive use of retention and tracking, emphasis on norm-referenced comparisons, and categorical eligibility requirements for special assistance that are unrelated to instructional needs. The knowledge to facilitate a thoughtful and effective restructuring of our system of schooling is available and is continuing to grow. Schools must be altered significantly to be relevant to a changing society and a changing population.

Considerations in Restructuring Education

There is no single model for restructuring schools. Decisions about restructuring should be made by partnerships of policy makers, administrators, and school personnel working within the goals and purposes of education shared by the community. However, a number of principles and underlying beliefs should be considered in any implementation efforts. Restructured schools should:

- Ensure a single educational system for all students that integrates special services and support programs with the regular education program.
- Ensure the rights of all students to an appropriate education and involve parents at all levels of decision making. An appropriate education should emphasize student outcomes that include maximized achievement, productive work attitudes and skills, and healthy personal and skill development.
- Involve parents in the education of their children and in schools in meaningful ways.
- Support meaningful school-based decision making and local flexibility. However, redesigned schools should be based on the most current psychological knowledge about learning and development, as well as effective instruction. Local decision making without an empirical base may lead to less than optimal results and even move in harmful directions.
- Ensure a challenging curriculum for all students that can be adapted individually as appropriate. High expectations should be held for all students. Instructional effectiveness should be the hallmark feature.
- Promote heterogeneous age-grade grouping and competency standards, such that all students of all given ages are not expected to master the same objectives in the same period of time. Seek alternatives to the use of retention as an academic intervention.

- Recognize that children learn in different ways and incorporate experiential and participative learning strategies into instruction that promotes understanding and problem-solving. Emphasize heterogeneous classes, cooperative learning, peer-assisted learning, and other adaptive education strategies that meet individual learning needs in diverse group settings.
- Ensure a caring personalized school environment that supports the social/emotional needs, as well as the academic needs of students. This environment should be reflected in design of programs, curriculum and attitudes of all staff. High quality youth–adult relationships should be evident.
- Encourage prevention and early intervention, including developmental early childhood programs for socio-economically disadvantaged children and other at-risk children.
- Emphasize assessment that focuses on the instructional and functional needs of the student, including progress in the curriculum, rather than assignment to categories or groups. Normative group assessment should be minimized in making decisions for and about students. Outcome measures should directly reflect success of specific school and student efforts and provide for direct and frequent monitoring of student progress.
- Maintain or expand existing levels of federal, state, and local funding, which provide instructional and support services in a manner that endures their availability for all students.
- Encourage active private/public cooperation, but not at the expense of adequate government funding of educational programs and services.
- Recognize that schools cannot accomplish their goals alone. Community supports to youth must be expanded: coordination among schools and community services to meet the health, welfare, and social needs of children and their families must be ensured, increased attention to school-work transitions for many students is essential.
- Find creative and new ways to recognize and reward excellence among teachers and students.

Next Steps

NASP joins other groups in recognizing the need to reexamine existing educational assumptions and systems. We believe the knowledge and research base is available to educate effectively all students in the mainstream of education. It is only through the united efforts of the many public and private stakeholders in the education of our youth that meaningful restructuring can occur. As we work collaboratively to explore viable options and alternatives, several dimensions that will influence the change process must be considered.

- Funding mechanisms must be examined for their impact on the access to and utilization of programs and services. If necessary, pilot efforts should be granted waivers from funding source regulations that restrict innovation on the basis of accountability for outcomes. Dual systems of record keeping and operation may be necessary until success of new models and paradigms can be demonstrated. In all cases, due process rights of students and parents must be protected.
- Policies at the local, state, and federal levels must be examined for the extent to which they constrain or facilitate effective instructional and schooling processes. Again, waivers for pilot efforts based on outcomes may be necessary.
- Attitudes of educators, parents, students, and the community are a significant factor in the speed and ease of organizational change. They must be considered and addressed so that they better support the restructuring process. Effective systems change requires efforts to empower those who are involved in it. All participants involved must feel some ownership for new programs and procedures and be part of the planning to restructure systems.
- Effective preservice and inservice training for all public school personnel is critical. New systems will require new skills. University training programs in all areas must be consistent with the most current knowledge base in order to prepare personnel with essential skills and attitudes for restructured schools. Substantive and ongoing inservice training must be provided for existing personnel to address skills required in restructured schools. The nature and delivery of preservice and inservice training may need to be redesigned.

NASP is eager to participate in discussion, planning, implementation, and evaluation of pilot restructuring efforts with schools, other organizations, and policy makers.

The Role of School Psychology in Educational Restructuring

For restructuring to occur, all education professions must work collaboratively in planning, implementing, and evaluating shared goals and outcomes. Each profession has important skills to bring to the process. NASP identifies here the knowledge and skills that school psychologists can contribute to educational restructuring. The knowledge base for the practice of school psychology provides an important empirical foundation for educational practice. Professional school psychologists are trained in human behavior, including learning, social, and emotional development. As data-oriented problem solvers, they are trained to approach problems from a systemic perspective and to consider the many interacting factors that influence educational attainment. As children's lives become more complex and as family, school, and other social structures change, this systemic view assumes greater importance. Working collaboratively with other educators, policy makers, parents, and students, school psychologists can make an important contribution to school effectiveness.

As an integral part of educational restructuring, school psychologists can:

- facilitate the process of planning for restructuring by applying expertise in organizational consultation, group process, problem solving and planning;
- integrate their services fully into the "general" education system;
- provide consultation and planning for effective classroom organization and social structures, as well as implementation of effective teaching principles;
- assist in modifying instructional practices to make them more appropriate to the social and academic needs of students with diverse backgrounds and characteristics;
- develop functional assessment procedures that measure instructional progress and learning outcomes;
- participate in developing curricula which promote mentally healthy children and adolescents, including topics of substance abuse prevention, sexuality, child care, relationship building, personal problem solving, suicide prevention and others;
- establish procedures for early identification of an intervention for learning, social, and emotional difficulties;
- help develop meaningful, collaborative partnerships between school and home and provide interventions, including parent education to families where needed.
- develop collaborative relationships with relevant community agencies, including medical, social, economic, and family support systems; and
- apply their training in psychology and research to studying practical problems of instructional and organizational effectiveness and to evaluating the outcomes of educational innovations.

Implementing New Roles

School psychological services should be examined in terms of their impact on students. Although extremely difficult to address, outcome measures also must be applied to psychological services and programs. In applying their own skills, school psychologists must seek to utilize the knowledge and skills of other education professionals in pursuing the challenge of restructuring schools to enhance the academic and personal success of all students. In addition, schools should strive to create the opportunities for school psychologists to perform these roles by implementing policies and funding strategies that promote services to all students.

Adopted April, 1989

Corporal Punishment

As the purpose of the National Association of School Psychologists is to serve the mental health and educational needs of all children and youth; and

The use of corporal punishment as a disciplinary procedure in the schools negatively affects the social, educational, and psychological development of students; and

The use of corporal punishment by educators reinforces the misconception that hitting is an appropriate and effective technique to discipline children; and

Corporal punishment as a disciplinary technique can be easily abused and thereby contribute to the cycle of child abuse; and

School psychologists are legally and ethically bound to protect the students they serve; and

Research indicates that punishment is ineffective in teaching new behaviors, that a variety of positive and effective alternatives are available to maintain school discipline, and that children learn more appropriate problem solving behavior when provided with the necessary models;

Therefore, it is resolved that the National Association of School Psychologists joins other organizations in opposing the use of corporal punishment in the schools and in other institutions where children are cared for or educated;

And will work actively with other organizations to influence public opinion and legislative bodies in recognizing the consequences of corporal punishment, in understanding and researching alternatives to corporal punishment, and in prohibiting the continued use of corporal punishment;

And will encourage state affiliate organizations and individual members to adopt positions opposing corporal punishment, to promote understanding of and research on alternatives to corporal punishment including preventive initiatives, and to support abolition of corporal punishment at state and federal levels.

Adopted by the NASP Delegate Assembly, April, 1986

Early Childhood Assessment

The purpose of the National Association of School Psychologists is to serve the educational and mental health needs of all children and youth, including infants and young children. Because the preschool and primary school years represent a period of rapid development, early identification and intervention for these children's psychological and developmental difficulties are essential, beneficial, and cost-effective. Furthermore, the accurate and fair identification of the developmental needs of young children is critical to the design, implementation, and success of appropriate interventions.

Relative to preschool and primary school children, evidence from research and practice indicates that:

- a limited number of technically adequate assessment procedures are available to conduct appropriate developmental assessments;
- standardized assessment procedures should be applied with great caution to decisions regarding school readiness, as such tools are inherently less accurate and less predictive when used with young children;
- multidisciplinary team assessments must include multiple sources of information, multiple procedures, and multiple settings in order to yield a comprehensive understanding of children's abilities;
- assessments should address family systems and home environments, which substantially influence the development of young children;
- parent–professional collaboration is crucial to decision-making as well as to the identification of child and family service needs;
- traditional categories of exceptionality are inappropriate for use in identifying special needs of young children;
- assessment of young children requires specialized training and skills beyond those required for the assessment of older children;
- longitudinal assessment is needed to evaluate and document progress or response to intervention over time; and
- functional assessment of an infant, young child, or family system's adaptive skills must guide early intervention strategies in meaningful ways.

Therefore, the National Association of School Psychologists will *promote* the following:

1. Early childhood assessment practices that are:

- developmentally appropriate, ecological, comprehensive, curriculum-based, and family-focused;
- conducted by a multi-disciplinary team;
- directly linked to intervention strategies designed for young children, rather than to categorical classification;
- based upon comprehensive, educational and/or behavioral concerns, rather than isolated deficits identified by individual scales;
- nondiscriminatory in terms of gender, ethnicity, native language, family composition, and/or socioeconomic status; and
- technically adequate and validated for the purpose(s) for which they are used.

2. Adoption of the philosophy of "parents as partners" to promote assessments and interventions for young children that include:

- full integration of parents into the assessment and intervention components of early childhood services;
- methods of naturalistic and systematic observation and information gathering;
- involvement of the family, home environment, daycare/preschool, and the community ecology as part of the comprehensive assessment to gather information and input from parents and caregivers.

3. Preservice and inservice education for school psychologists to address:

- normal as well as atypical developmental patterns of young children;
- practices, procedures, and instrumentation appropriate for screening and assessment of young children, their families, and their environments;
- the use of empirically sound procedures and technically adequate instruments with demonstrated treatment utility;
- the selection of assessment techniques and utilization of findings from such assessments for the design, implementation, and efficacy evaluation of interventions;
- standards for early childhood psychological and educational assessment, including legal, ethical, and professional issues; and
- noncategorical service delivery for young children and their families.

Adopted by the NASP Delegate Assembly March 24, 1991

This chapter provides the essentials for alternative assessment and intervention design for young children. The empirical foundations of early intervention, an appraisal of traditional preschool service delivery, and practitioner issues are discussed.

Danielson, E., Lynch, E., Moyano, A., Johnson, R., & Bettenburg, A. (1988). *Assessing young children.* Washington, DC: NASP.
This document was acquired from the Minnesota Department of Education and offers information about best practice in screening and assessment of young children. A critique of commonly used procedures is included, as well as standards for selecting and interpreting appropriate procedures. Naturalistic observation and family assessment are encouraged.

McLoughlin, C., & Rausch, E. (1990). Best practices in kindergarten screening. In A. Thomas & J. Grimes (Eds.), *Best practices in school psychology–II.* Washington, DC: NASP.
This chapter summarizes appropriate approaches and skill areas to consider as part of a kindergarten screening program. Problems unique to this age group are included, as well as specific techniques that will lead to developmentally appropriate decision-making.

NASP. (1987). *Early Intervention Services* (Position Statement adopted by the Delegate Assembly, September 1987).
This position statement calls for developmentally appropriate intervention services, comprehensive evaluation of all important aspects of the development of young children, reliable and valid screening, flexible assessment procedures, noncategorical services, and training opportunities for professionals. A supporting paper citing research and policy accompanies this position statement.

Ohio Department of Education. (1988). *Early childhood identification process; A manual for screening and assessment.* Washington, DC: NASP.
This manual uses an intervention framework to describe a wide range of approaches to early identification and referral of at-risk preschool children.

Paget, K. D. (1990). Best practices in the assessment of competence in preschool-age children. In A. Thomas & J. Grimes (Eds.), *Best practices in school psychology–II.* Washington, DC: NASP.
The author summarizes best practices in preschool assessment from an ecological perspective and within the provisions of PL 99-457. Qualitative differences in the approach to assessing young children versus older children are emphasized, along with areas where school school psychologists may need additional training. Support is provided for regarding the family and the child's natural environment as appropriate contexts for assessment.

School Psychology Review, 15(2). (1986). Mini-series on preschool assessment.
This mini-series offers articles covering conceptual as well as practical issues, emphasizing an ecological model. A full range of issues is addressed, including family, curriculum-based developmental procedures, cognition, social-emotional development, and neuropsychology.

Early Childhood Care and Education

The National Association of School Psychologists recognizes that the futures of children are affected by factors that occur early in life. Affordable, high quality early childhood care and education represent major needs of today's and tomorrow's children and families and can benefit children, their families, and society in terms of prevention of later learning and behavior problems, increased family self-sufficiency, and reduced costs for special education, welfare, and other public assistance.

The need for affordable, quality early childhood education and care is supported by the following findings:

- The majority of families in the United States have two parents or a single head of household who work outside the home because of economic necessity and only 7% of households now fit the pattern of a breadwinner father and housewife mother, with dependent children.
- Poverty rates in the United States have increased from 11.6% in 1979 to 14% in 1985. In 1983, 22% of all children lived in households below the poverty level. About 20% of economically disadvantaged children are poor even though they have two parents or a single head of household who work full-time.
- Governmental support for child care has decreased. Many families, particularly single-parent families, cannot afford quality child care, even when parents work. The average yearly child care cost of $3,000 represents 45% of the annual income for one parent working at minimum wage. The cost of child care results in a system where low-income families have few child care choices.
- Many children are left unsupervised or in poor quality child care and may be vulnerable to psychological and physical risks that affect their development and safety. Estimates indicate that 2 to 7 million children aged 6 to 11 years are unsupervised after school. About 70% of family day care programs are not licensed or are not required to be licensed.
- Inadequate child care options can have a broad and costly social impact by contributing to parents' inability to acquire or maintain employment, inability to participate fully in job-assistance programs, and higher absenteeism and lower productivity on the job.

Affordable, high quality early childhood care and education can benefit children, families, and society. Positive outcomes of quality child care and education programs are most pronounced for economically disadvantaged children and families. Although more research is needed, existing research findings support potential benefits in each of these areas:

Children

Participation in quality early childhood programs can result in:

- prosocial behaviors of young children such as more self-regulation, verbalization, and competent play and exploration;
- short-term gains in intelligence test scores, especially by economically disadvantaged children; and
- long term benefits for economically disadvantaged children such as decreased placement in special education and lower retention rates.

Families

- Participation in early childhood programs, particularly those which provide family services, can result in factors such as more positive maternal attitudes regarding their children and themselves and better mother–child interactions.
- Availability of early childhood programs can promote increased family financial self-sufficiency.

Society

Availability of early childhood programs can result in:

- reduction of costs to society, such as costs related to special education, public assistance, crime, and welfare; and
- increased business productivity related to less turnover and absenteeism and improved job productivity in parents.

The benefits identified above are associated with high quality programs. Advanced development of children in early childhood programs is associated with the quality of the programs in terms of factors such as group size, adult–child ratios, curriculum, adult–child interaction, and training and education of the staff. Family involvement, interventions, and services can also be effective components of early childhood programs.

Research concerning participation in after-school care programs by school-aged children is extremely limited at this time, but suggests promising benefits of these programs, including increased social adjustment and academic achievement.

The need for early childhood care and education cannot be denied; furthermore, affordable, high quality child care can promote the futures of children and their families. Therefore, it is resolved that the National Association of School Psychologists will:

1. Support programs and government funding which provide equal access to affordable, high quality early childhood care and education for all children and their families. Tax rebates and credits are not substitutes for government funding of accessible, quality programs.

2. Encourage the development, implementation, and ongoing evaluation of standards for child care quality including:

a. developmentally appropriate curricula.

b. appropriate group sizes and adult–child ratios.

c. adequate staff selection, education, training, and compensation.

d. appropriate physical facilities.

e. responsiveness to individual differences and cultural and language diversity.

f. appropriate access to special and related services or specialists.

g. non-discriminatory practices.

3. Support and assist with the development of alternative forms of child care, including in-home and out-of-home care, that meet the preferences and needs of families.

4. Support public regulation of all forms of out-of-home care to insure the quality of programs and safety of children.

5. Support comprehensive programs, beginning at the prenatal period, which include involvement of and interventions for parents and families, and health, nutrition, and related services.

6. Support continued research investigating factors related to child care, including effects of day care and family dynamics on children's development, methods of improving child care, effects of alternative forms of child care and family services, long-term benefits of child care for children and families, and economic benefits of child care for society.

7. Encourage the development of programs which help families evaluate their child care needs and goals and provide families with information about child care arrangements and standards for quality.

8. Encourage the establishment of partnerships between schools and other programs and organizations which provide accessible, comprehensive early childhood services for all families who need them.

9. Support continued research investigating the effectiveness of after-school care programs for school-aged children.

10. Encourage state affiliate organizations to adopt this position statement and school psychologists to participate in developing affordable, quality child care programs and delivering effective services within the programs.

Adopted by the NASP Delegate Assembly April, 1989

Early Intervention Services

Whereas the purpose of the National Association of School Psychologists is to serve the mental health and educational needs of all children and youth; and

Research has shown that early intervention with handicapped and at-risk infants, toddlers, and preschool children is effective in terms of benefits to children, benefits to their families, and long-term cost savings to school districts and society; and

Many public schools are now or will soon be involved in providing special education and related services to these children and their families as a result of federal and state legislation;

It is is resolved that the National Association of School Psychologists supports the expansion and improvements of services to handicapped and "at-risk" infants, toddlers, and preschool children.

NASP will encourage school psychologists to take part in efforts of national, state, and local levels to:

1. Assure that programs for young children are built on recognition of the needs and developmental characteristics of these children which make them different from older children.

2. Work with school administrators, teachers, and parents to develop programs that attend to all important aspects of the development of young children, including cognitive, motor, self-help, socioemotional, and communication development.

3. Promote programs which provide reliable and valid means of screening young children for possible handicapping and "at-risk" conditions as early as possible.

4. Encourage the use of flexible team assessment approaches which take into account the unique attributes and variability of young children and the influence of home and family factors on their development.

5. Support the provision of necessary individualized services without attempting to assign labels for specific handicapping conditions.

6. Work toward establishing programs which provide a broad spectrum of options for intervention, opportunities for parents to receive support and assistance, and mainstreaming opportunities wherever possible.

7. Encourage university programs, professional associations, public schools and other continuing education providers to provide opportunities for practitioners to receive professional developmental experiences that adequately prepare them to serve the needs of young children and their families.

8. Help establish networks of communication and collaboration among the many agencies that provide service to infants, toddlers, and preschool children.

9. Advocate for the provision of state and federal funding to assure that appropriate programs for infants, toddlers, and preschoolers are provided.

Adopted by the NASP Delegate Assembly September, 1987.

Students with Attention Deficits

The National Association of School Psychologists advocates appropriate educational and mental health services for all children and youth. NASP further advocates noncategorical models of service delivery within the least restrictive environment for students with disabilities and students at risk for school failure.

NASP recognizes that there are students in schools with academic and adjustment problems who exhibit a constellation of behaviors commonly associated with ADD/ADHD (Attention Deficit Disorder/Attention Deficit Hyperactivity Disorder). NASP believes that attention deficits are not a unitary condition, and that they are not reliably diagnosed. NASP also recognizes that it is difficult to distinguish attention deficits so severe as to require special education to which all students are susceptible.

Longitudinal data suggest that the problems associated with attention deficits present at an early age, may change over time, and that they may persist into adulthood. Therefore, NASP believes that interventions must be designed within a developmental framework. Furthermore, recognizing that these students are at particular risk for developing social-emotional and learning difficulties, NASP believes problems should be addressed early to reduce the need for long-term special education.

NASP believes that students with attention deficits can be provided special education services as appropriate under disability categories currently existing in EHA/IDEA. While concern has been expressed that children with attention deficits served in existing categories will not receive the most appropriate instruction for their unique needs, research indicates that disability categories or areas of teacher certification have no significant effect on instructional methods or on effectiveness of service.

NASP believes that excessive emphasis on assessment and diagnosis at the expense of developing and monitoring effective interventions is not in the best interests of children. Assessment of youngsters with possible attention deficits should include intervention assistance to students and their teachers as prerequisites to a formal assessment process.

NASP believes that effective interventions should be tailored to the unique learning strengths and needs of every student. For children with attention deficits, such interventions will often include the following:

1. Classroom modifications to enhance attending, work production, and social adjustment;

2. Behavior management systems to reduce problems in areas most likely to be affected by attention deficits (e.g., unstructured situations, large group instruction, transitions, etc.);

3. Direct instruction in study strategies and social skills, within the classroom setting whenever possible to increase generalization;

4. Consultation with families to assist in behavior management in the home setting and to facilitate home–school cooperation and collaboration;

5. Monitoring by a case manager to ensure effective implementation of interventions, to provide adequate support for those interventions, and to assess programs in meeting behavioral and academic goals;

6. Education of school staff in characteristics and management of attention deficits to enhance appropriate instructional modifications and behavior management;

7. Access to special education services when attention deficits significantly impact school performance;

8. Working collaboratively with community agencies providing medical and related services to students and their families.

NASP believes appropriate treatment may or may not include medical intervention. When medication is considered, NASP strongly recommends:

1. That instructional and behavioral interventions be implemented before medication trials are begun;

2. That behavioral data be collected before and during medication trials to assess baseline conditions and the efficacy of medication; and

3. That communication between school, home, and medical personnel emphasize mutual problem solving and cooperation.

NASP believes school psychologists have a vital role to play in developing, implementing, and monitoring effective interventions with students with attention deficits. As an association, NASP is committed to publishing current research on attention deficits and to providing continuing professional development opportunities to enhance the skills of school psychologists to meet the diverse needs of students with attention deficits.

Adopted by NASP Delegate Assembly September, 1991.

Students with Emotional/Behavioral Disorders

The National Association of School Psychologists is committed to promoting effective services to meet the educational and mental health needs of all students. Students with emotional and/or behavioral problems constitute an underserved population within the American educational and mental health systems. These problems interfere with the acquisition of academic and social skills and negatively impact adult adjustment. Therefore, early identification and intervention for students with emotional and/or behavioral problems are essential.

Definition

The National Association of School Psychologists has endorsed the following definition of Emotional/Behavioral Disorders developed by the National Mental Health and Special Education Coalition:

Emotional or Behavioral Disorder (EBD) refers to a condition in which behavioral or emotional responses of an individual in school are so different from his/her generally accepted, age-appropriate, ethnic, or cultural norms that they adversely affect educational performance in such areas as self-care, social relationships, personal adjustment, academic progress, classroom behavior, or work adjustment.

- EBD is more than a transient, expected response to stressors in the child's or youth's environment and would persist even with individualized interventions, such as feedback to the individual, consultation with parents or families, and/or modification of the educational environment.
- The eligibility decision must be based on multiple sources of data about the individual's behavioral or emotional functioning. EBD must be exhibited in at least two different settings, at least one of which is school-related.
- EBD can co-exist with other handicapping conditions, as defined elsewhere in this law (i.e., Education of Handicapped Act).
- This category may include children or youth with schizophrenia, affective disorders, anxiety disorders, or with other sustained disturbances of conduct, attention, or adjustment.

Assessment and Identification

The identification of a student as emotionally/behaviorally disordered is a serious event that can have lifelong educational, social, and vocational consequences. It is essential that the identification reflects a true handicapping condition, and not the intolerance or insensitivity to individual differences, the impact of unrelated disabilities, or temporary situational factors. The primary purpose of the assessment should be identification of needs/goals and related intervention, not labeling.

The identification process should proceed from the least intrusive to more intrusive procedures. Many behavior problems can be addressed through simple non-intrusive means within the regular education setting. Should behavior problems be more pervasive and intense, more intrusive procedures will be needed, involving personnel beyond the regular education setting. A small number of students will require comprehensive special education assessment, placement, and intervention.

Assessment of emotional/behavioral problems under the above definition should address duration, severity, and pervasiveness of problem manifestations, and response to intervention. Furthermore, the assessment should be collaborative and interdisciplinary, and include:

- Multiple sources of information, including such procedures as structured interviews, systematic and structured observations, behavior checklists and rating scales, self-reports, work samples, and standardized assessment instruments when appropriate. These methods should be demonstrably reliable and valid, and developed for the purposes for which they are used.
- Information from the home and community in relation to the child's behavioral and emotional functioning, cultural norms and expectations, and relevant family, health, and developmental history.
- The determination of a significant impairment in at least one area of school adaptive behavior (such as social skills, organizational skills) and significant impairment in adaptive behavior outside of the school setting (such as vocational skills or interpersonal relationships).
- The analysis of alternative factors underlying the child's behavioral or emotional responses.
- Documentation of the student's response to intervention(s).
- A direct link to intervention planning.

The school psychologist should be involved in all school-based emotional/behavioral disorder assessments. This involvement could include any or all of the following:

- Review of referral and screening information.
- Consultation in the planning of assessment and/or intervention.
- Interpretation of assessment data.

- Linking assessment data to intervention planning, implementation, and evaluation.

Intervention

Emotional/Behavioral Disorder is a dimensional rather than categorical condition. Emotional and/or behavioral disorders that impair school performance exist along a continuum of severity. Most students will experience behavioral and/or emotional difficulties at some time in response to transient situational and developmental stressors. Many students' needs can be effectively addressed through prevention programs, consultation with teachers and parents, short-term counseling, and/or interventions within the regular classroom setting. Such interventions should be empirically-based interventions and of sufficient duration to maximize opportunities for success. Systematic evaluation of interventions is also needed to determine effectiveness, treatment integrity, and the need for modification or additional strategies.

Characteristics of interventions for emotional and behavioral problems should include the following:

- Choice and planning of interventions based on empirical data documenting effectiveness in dealing with identified problems;
- A direct relationship to assessment information;
- A plan to evaluate effectiveness in yielding desired results; and
- Continuous monitoring and adjustment as needed to ensure efficiency and accuracy of services.

Program Placement

Identification is not synonymous with placement in a special education program; and identification does not negate the school's obligation to provide services in the Least Restrictive Environment (LRE). The LRE is the learning environment that best meets the academic and social needs of the student with any appropriate modification and/or related services. The LRE may be the regular education classroom or another setting. Special education programs exist on a continuum from least to most restrictive in relation to the regular education classroom, including resource rooms, self-contained classrooms, and residential programs. Frequently, students requiring more specialized interventions and placements also require coordination of services between school-based and community-based programs.

At each level, school psychologists should consult with teachers, parents, and agencies; provide counseling and social skills training; and continue to develop, implement, and evaluate intervention procedures. Furthermore, school psychologists endorse alternatives to categorical labeling and placement and help ensure that only those students who cannot be served appropriately in the regular classroom, based upon reliable and valid data, are considered for more restrictive programs.

In determining the student's need for placement in a more restrictive setting, the following conditions must be considered.

- Duration — The condition must exist for an extended period of time and not be a short-term response to specific situational stressors.
- Severity — The condition must significantly effect school performance as reflected by academic achievement, acquisition of social skills, and interpersonal relationships within the school setting.
- Pervasiveness — The behaviors of concern occur across situations.
- Resistance to Intervention — The behaviors of concern continue despite the appropriate, individualized application of intervention strategies provided within the regular classroom.
- Exclusionary Factors — The behaviors of concern are not due to transient situational variables, cultural or linguistic differences, or primarily the result of other handicapping conditions. Furthermore, intervention and placement are not sought primarily as disciplinary actions or as efforts to resolve conflicts between individuals or agencies.

Importance of Collaboration

The provision of appropriate services to students with Emotional/Behavioral Disorders requires efficient and effective coordination of assessment and intervention strategies. The multi-disciplinary team is essential to the comprehensive evaluation process and to the determination of eligibility for special education and related services. The National Association of School Psychologists recognizes the importance of collaboration across all service providers to ensure that services are designed and carried out in a manner that is empirically-based, culturally sensitive, and of the greatest benefit to the student and family. The National Association of School Psychologists endorses alternatives to categorical labeling. School psychologists are aware of the long-term harmful effects of such labeling. Thus, only those students who cannot be educated appropriately in the regular classroom, based on reliable and valid data, are considered for more restrictive placements.

Employing School Psychologists for Comprehensive Service Delivery

The National Association of School Psychologists supports policies and practices which enhance the education of all students. NASP is concerned about staffing policies which are detrimental to the best interests of the child, family, and school system as a whole. During times of economic crisis and personnel shortages, school districts may consider alternatives to employing their own school psychologists, such as contracting out for services or general staff reductions It is essential that administrators and policymakers understand the nature and potential limitations of these options and the importance of maintaining professional standards in order to make cost-effective decisions which do not sacrifice the quality or availability of services to students.

Independent contracting for school psychological services includes a variety of arrangements, such as privatization and subcontracting through other public agencies. Some school districts have implemented contracts with agencies or individuals which shift the delivery of services from the public to the private sector, or may contract services through public cooperative (intermediate) units, or may supplant school-based services with "co-located" services of community agencies.

NASP does not oppose the provision of comprehensive school psychological services through intermediate educational agencies. In fact, NASP recognizes that such units often represent the most viable means of ensuring appropriate services. However, NASP opposes independent contracting as a general practice if it compromises the delivery of comprehensive services as required by professional standards and federal law and if contracting supplants or decreases the availability of services delivered by district-employed school psychologists.

NASP's professional standards require that "employing agencies assure that school psychological services are provided in a coordinated, organized fashion, and are deployed in a manner which ensures the provision of a comprehensive continuum of services . . ."[1] In addition, the federal mandates of the Individuals with Disabilities Education Act (IDEA), formerly PL 94-142, require that the evaluation and placement of students with disabilities is comprehensive, multi-faceted, and determined by a multidisciplinary team. This process stresses the need for educational specialists to work with each other in the educational environment and to gather input from numerous sources, including observation of the student within the learning environment, consultation with school personnel regarding educational performance, consultation with parents, and individualized assessment of the student's skills.

Both NASP and the American Psychological Association recognize the specialized training in school psychology as different from the specialized training in other specialty areas, such as clinical and industrial psychology. The independent contractor who is not a trained school psychologist may be a skillful clinician, but lack essential knowledge, expertise, and experience to gather appropriate data in the school context and to facilitate a collaborative, comprehensive approach with the other members of the educational team.

School psychologists employed by school districts:

- offer cost-effective services including early prevention and intervention activities which can eliminate the need for many costly evaluations and placements;
- are readily available to school personnel and students in times of crisis;
- understand school issues form a systems perspective;
- are sufficiently familiar with the students, staff, legal requirements, and policies of the school system to provide support, consultation, and intervention where day-to-day knowledge is essential to communication and to defusing potential dangerous or adversarial situations; and
- provide a wide range of services not easily or cheaply purchased via private contracts, such as reviews of records, consultation with parents and school personnel, ongoing systematic classroom observations, inservice training, program planning and evaluation, and participation on multidisciplinary teams.

Contractual services may be appropriate in limited circumstances in which an outside contractor supplements the regular services of the district's school psychologists or provides services which are otherwise unavailable or impractical. Such circumstances include:

- specific situations where specialized training and experience beyond what is typically available in the school district is required in order to provide appropriate service to the student or district, such as with low incidence disabilities or the provision of clinical home-based services through shared funding;
- situations where a very small district is unable to support the funding of a full-time psychologist and must seek an alternative arrangement such as con-

tracting through an independent services provider; and

- situations where a personnel shortage creates a temporary need to obtain services from available sources such as private providers.

Any contractual agreement should meet the standards established by NASP (Standards for the Provision of School Psychological Services, 1992, Section 3.4, "Contractual Services") and follow the guidelines of the APA/NASP Inter-organizational Council, and ensure that:

- due process rights of students are upheld;
- the amount and quality of psychological services is increased, not decreased; and
- the agreement does not result in any loss of legitimate employee rights, benefits, or wages.

Psychologists hired under independent contract to provide services in the schools should hold at least the same credentials and should be expected to practice within the same professional and ethical standards as school-employed psychologists.

The National Association of School Psychologists is committed to enhancing educational opportunities for all students through the organized delivery of comprehensive school-based psychological services. NASP further recognizes that such services can be delivered in a variety of ways without compromising the rights and needs of students. However, in most situations, the most cost-effective, professionally accountable services will be those delivered from employees within the school district.

NASP therefore urges school administrators and school board members to consider the legal, educational, and long-term financial ramifications of any shift of services away from the school district, and to seek more cost-effective models of service delivery which do not decrease the availability of school-based psychologists. We further urge school psychologists to work with administrators, collective bargaining units, and professional associations to help develop strategies for the delivery of cost-effective services which maintain their rights as employees and enhance educational outcomes for all students.

Finally, NASP urges school psychologists and other educators to empirically evaluate the cost-effectiveness of current and proposed models of service delivery and to establish ongoing program evaluation of all providers of school psychological services.

Standards for the Provision of School Psychological Services, National Association of School Psychologists, 1992.

Guidelines: Contractual Services in School Psychology. Statement developed by the APA/NASP Inter-Organizational Council (IOC). Endorsed by the NASP Delegate Assembly, March 27, 1992.

Adopted by the NASP Delegate Assembly, April 18, 1993.

Home–School Collaboration

The National Association of School Psychologists is committed to increasing the academic, behavioral, and social competence of all children and youth. To meet the educational and mental health needs of all students, partnerships between parents and educators are needed. Collaboration between home and school is essential if students are to benefit optimally from the schooling process. Early implementation of home–school partnerships helps to focus efforts toward prevention.

Parents play an important role in school, and research has demonstrated that:

- home environment influences student performance in school;
- parent participation in education is associated with students' positive attitudes and behavior, long-term achievement gains, better attendance, increased completion of school work, higher grades, and improved test scores;
- specific intervention programs have successfully used parents to change their children's academic and behavioral performance;
- family involvement is essential to address specific referral concerns; and
- children achieve more when there is a match between expectations, rules, and interaction styles in the home and school environments.

Educators need to support families, and research has demonstrated that:

- parents want their children to be successful in school, but some parents do not know how to assist their children;
- parents seek guidance from educators;
- parents want to be partners with educators in the education of their children;
- parents' participation in education includes involvement at home and at school; and
- parents' participation increases when they see their participation directly linked to the success of their children.

Societal factors impinge upon children's school performance, including:

- increased cultural diversity;
- increased poverty and unemployment;
- increased drug abuse, crime, and violence; and
- change in the concept of family (e.g., divorce, remarriage, single parenting, extended families, neighbors).

Society is increasingly recognizing that schools cannot meet the educational and socialization needs of all children without the sharing of resources provided by the family and community. The National Association of School Psychologists supports creating collaborative partnerships between parents and educators for the purpose of increasing students' academic, behavioral, and social competence. Collaborative partnerships are characterized by:

- meaningful dialogue and sharing of information;
- mutually agreed upon goals;
- sharing of resources; and
- shared decision-making

The philosophy of partners working together toward a common goal with shared power characterizes home–school collaboration. Home–school collaboration is an attitude, not an activity and occurs when parents and educators share common goals and responsibilities, and are seen as equals. Effective partnerships recognize that all parent/families have strengths rather than identifying deficits. Effective partnerships between parents and educators have an additive, positive effect on students' performance.

NASP encourages school psychologists to take part in national, state, and local efforts to:

- define parent involvement in education to include true partnerships between home, school, and community;
- advocate, with school systems, for increased collaboration between educators and parents regarding the schooling process.;
- reach out to all parents and identify strategies to encourage participation by uninvolved parents;
- recognize parents as experts in relationship to their children's behavior;
- avoid labeling families by using an approach which builds on family strengths;
- work with other organizations to promote home–school–community partnerships to increase students' performance in school;
- pursue continuing education on such topics as family interventions, models of home–school collaboration, models of parent education/training, child development and family developments, and understanding cultural and ethnic differences;
- develop parent involvement programs that provide parents with options to be meaningfully involved and are sensitive to individual parents' needs, resources, and time constraints, including those par-

ents who may have been disenfranchised from the school due to their own negative experiences;

- promote communication among families, community, and school personnel to increase students' success in school;
- provide training and support to parents from all cultures on effective strategies for communicating with educators;
- provide training to educators to increase their understanding of culturally and ethnically diverse families;
- develop home–school collaboration programs that facilitate family–school meetings as parents and educators engage in problem solving about individual students;
- provide direct services to parents regarding techniques to promote students' academic and behavioral success in school and the community; and
- consult with parents and teachers to coordinate home and school efforts and serve as a liaison to maintain information exchange and sharing of resources between home, school, and community.

Adopted by the NASP Delegate Assembly, September, 1992.

Inclusive Programs for Students with Disabilities

The Individuals with Disabilities Education Act (IDEA) created significant educational opportunities for students with disabilities and established important safeguards that ensure the provision of a free, appropriate education to students with special needs. NASP strongly supports the continuation and strengthening of this mandate. NASP also recognizes the need to continually evaluate the effectiveness of all aspects of our educational system and to promote reform when needed.

Problems with the Current System

NASP also recognizes that the special education system that evolved under this mandate includes a number of problems that create unintended negative outcomes for some students. These include:

- A referral and evaluation system that does not function as originally intended. Some of the weaknesses of this system include: (a) an inability to reliably differentiate among categories of students with disabilities; (b) a lack of evidence that students grouped by category learn differently or are taught differently; and (c) a classification system that lacks reliability, utility, and acceptance by many parents and professionals.
- Inequities in implementation of the least restrictive environment provisions of IDEA. Data suggests that the restrictiveness of many special education placements is not based upon the severity of students' disabilities, but may instead result from the configuration of the service delivery system that is available in the community.
- Concerns that traditional special education programs are not effective in terms of learner outcomes.
- Overly restrictive special education programs housed in separate schools or "cluster" sites that result in social segregation and disproportionate numbers of students with disabilities being grouped together. For example, some students, especially those with more severe disabilities, must attend separate schools to receive appropriate special services. Many parents and professionals feel that it is inherently inequitable that some students must leave their neighborhood schools and communities to receive appropriate services.

A Call for Inclusive Schools

NASP, in its continuing commitment to promote more effective educational programs for ALL students, advocates the development of inclusive programs for students with disabilities. Inclusive programs are those in which students, regardless of the severity of their disability, receive appropriate specialized instruction and related services within an age-appropriate general education classroom in the school that they would attend if they did not have a disability. *NASP believes that carefully designed inclusive programs represent a viable and legitimate alternative on the special education continuum that must be examined for any student who requires special education.*

Potential Benefits

Some of the benefits of inclusive programs include:

- typical peers serving as models for students with disabilities;
- the development of natural friendships within the child's home community;
- learning new skills within natural environments, facilitating generalization of skills;
- students with disabilities existing in "natural" proportions within the school community;
- all students learning to value diversity; and
- general education classrooms that are better able to meet the needs of all students as a result of additional instructional resources, a more flexible curriculum, and adapted instructional delivery systems.

Developing Inclusive Programs

In advocating for the development of these programs, NASP takes the position that:

- Inclusive programs must provide all the services needed to ensure that students make consistent social and academic gains.
- General education teachers, special education teachers, school psychologists, other related services providers, and parents must collaborate to ensure appropriate services for all students and to ensure that all programs are based upon a careful analysis of each student's needs.
- Outcome-based data on inclusive programs must be collected to ensure that students with and without disabilities are making consistent educational progress.
- All educators involved in implementing inclusive programs must participate in planning and training activities. Knowledge and skills in effective collaboration, curriculum adaptation, developing supportive social relationships, and restructuring special services are but a few of the areas in which

skills are needed. Training based upon the needs of the staff involved in planning these programs is essential.

The Role of the School Psychologist

School psychologists can provide effective leadership in the development of inclusive programs. School psychologists have training and experience in collaborative consultation, disabilities, intervention design and curriculum adaptation, modification of learning environments, program evaluation, and other issues critical to effective inclusive programs. Because of this expertise, school psychologists are in a unique position to assist schools in assessing student needs, reallocating existing resources, and restructuring service delivery systems to better meet the educational and mental health needs of all students. School psychologists can foster the development of inclusive schools by:

- providing meaningful support and consultation to teachers and other educators implementing inclusive programs;
- distributing articles and research to fellow educators and district committees responsible for educational restructuring;
- leading or serving as members of groups that are evaluating or restructuring education programs;
- planning and conducting staff development programs that support inclusion;
- providing information on needed changes to legislators and state and federal policy-makers; and
- collecting and analyzing program evaluation and outcome-based student data.

Changing our Schools

NASP recognizes that the current framework of special education policies and regulations is often incompatible with inclusive programs. Consequently, NASP joins with the National Association of State Boards of Education in calling for a fundamental shift in the policies which drive our compensatory education system. Changes are required in:

- The system used to identify and evaluate students with special needs. Categorical labeling systems are not only unreliable and stigmatizing, they are unnecessary in an inclusive system.
- The current special education funding system. The link between funding and placements must be severed. Many aspects of the funding system are driven by labels and program locations rather than by student needs.

NASP recognizes that the shift toward more inclusive schools will require profound changes in the ways in which schools are organized. We are committed to working with parents, other professional groups, and state and national policy-makers in creating new funding and regulatory mechanisms that promote effective programs within neighborhood schools and ensure that students with special needs continue to receive appropriate resources. We endorse a process of planned change that involves all stakeholders in research, planning, and training to ensure that our nation's schools can attain excellence for *all* of our children.

Adopted by the NASP Delegate Assembly, April 17, 1993.

Minority Recruitment

As the purpose of the National Association of School Psychologists is to serve the mental health and educational interests of all youth,

As the proportion of ethnic minority children is increasing in the total school population, and

As there are disproportionately few ethnic minority school psychologists to serve both regular and special education students, and

As NASP is committed to the recruitment of ethnic minority group members,

Therefore, it is resolved that the National Association of School Psychologists will work actively to increase the numbers of ethnic minority school psychologists working with children and as trainers in school psychology programs;

And will advocate the use of recruitment procedures that are known to be successful, such as flexible admission standards, financial support, and active outreach efforts;

And will encourage its membership to assist school psychology training programs in recruiting ethnic minority group members into the profession;

And will encourage school psychology training programs to conduct research and develop the most appropriate strategies to recruit, train, and graduate greater numbers of ethnic minority individuals from their programs.

Adopted by the NASP Delegate Assembly, September, 1987.

Pupil Services: Essential Education

The goal of education is to prepare young people to become literate and motivated workers, caring family members and responsible citizens. Professionals concerned with education further recognize that — in addition to intellectual challenges — students must overcome personal, social, organizational, and institutional challenges that could place them at risk for educational failure. Intervention that addresses these challenges is essential.

Pupil service teams that include professional counselors, school psychologists, and school social workers are trained in such interventions and in removing barriers to learning. These professionals are partners with other educators, parents and the community in accomplishing this objective and in providing optimum teaching and learning conditions for all students in a total education program.

The value of pupil services has long been recognized by federal, state, and local governments. In 1988, the pupil services team concept was again reinforced in federal law. In the Hawkins-Stafford Elementary and Secondary School Improvement Amendments of 1988 (P.L. 100-297), the following definition was included:

> "The terms 'pupil services personnel' and 'pupil services' mean school counselors, school social workers, school psychologists, and other qualified professional personnel involved in providing assessment diagnosis, counseling, education, therapeutic, and other necessary services as part of a comprehensive program to meet student needs, and the services provided by such individuals."

Clearly, pupil services are most effectively delivered through the team approach. The complex needs of students demand the comprehensiveness implied by uniting the skills of trained professionals. Through teamwork, school psychologists, school social workers, school counselors, and other pupil services providers work together to provide coordinated services for students and their families. The pupil services team approach is based on the following concepts:

- Pupil services programs should be developed from identified needs of students, parents, staff, and administrators.
- All pupil services are related and must be coordinated for optimum effectiveness.
- Pupil services demand developmental, preventive, and remedial emphases, thus requiring the contributions of skilled professionals.
- Pupil services facilitate effective linkages between the school community and external community resources.
- Program evaluation is critical to pupil services teamwork.
- The teamwork required for achievement of pupil service objectives mandates trust, open communication, mutual respect, ongoing collaboration, and effective coordination.

We believe that this team approach for pupil services can establish a national precedent for state and local initiatives. Such initiatives would be designed to provide vital services to all young people in our schools. Our purpose is to support the efforts of counselors, psychologists, social workers, and other pupil service professionals in providing a coordinated delivery system designed to serve this country's school-aged youth.

Through this statement, our respective organizations reaffirm the pupil services team approach as integral to the educational process. We further signify our commitment to continue collaborative efforts. We invite other pupil service professionals to join with us in this alliance.

This statement issued jointly by the American Association for Counseling and Development, the American School Counselor Association, the National Association of School Psychologists, and the National Association of Social Workers.

Racism, Prejudice, and Discrimination

The National Association of School Psychologists is committed to promoting the rights, welfare, educational, and mental health needs of all students. This can only be accomplished in a society which ensures that all people, including children and youth, are treated equitably without reference to race, ethnicity, religion, or gender. NASP believes that racism, prejudice, and discrimination are harmful to children and youth because they can have a profoundly negative impact on school achievement, self-esteem, personal growth, and ultimately the welfare of all American society.

A discussion of multicultural issues requires a definition of terms. The following definitions apply to the terms used in this position statement (adopted from the Multicultural Project for Community Education, Cambridge, MA and Washington, DC).

Prejudice: Prejudice is an attitude, opinion, or feeling formed without prior knowledge, thought, or reason.

Discrimination: Discrimination is differential treatment that favors one individual, group, or object over another. The source of discrimination is prejudice, and the actions are not systematized.

Racism: Racism is racial prejudice and discrimination — supported by institutional power and authority — used to the advantage of one race and the disadvantage of other race(s). The critical element of racism which differentiates racism from prejudice and discrimination is the use of institutional power and authority to support prejudice and endorse discriminatory behaviors in systematic ways with far-reaching outcomes and effects.

Research indicates that students who are the victims of racism, prejudice, and discrimination develop feelings of worthlessness; deny membership within their own group, identify with the dominant group, develop prejudice against other ethnic minorities, achieve less in school and have lower aspirations for the future, and drop out of school in increased numbers.

As a nation, we must be committed to replacing racism, discrimination, and prejudice with attitudes and behaviors that reflect fairness and cooperation. Children must learn tolerance and cooperation, and this learning must begin at an early age. The National Association of School Psychologists urges all educators and community leaders to:

- promote policies to establish and maintain racial and cultural diversity among school personnel;
- take an active role in teaching students pluralistic values, using strategies such as cultural sensitivity training, cooperative learning, and conflict resolution training;
- discuss racism, prejudice, and discrimination with students of all ages;
- provide students with an opportunity to learn about culturally and ethnically diverse groups;
- employ curricula which give students the opportunity to explore issues of self-identity; and
- develop self-esteem programs for all students to promote self-respect and respect for others.

As mental health professionals, it is our charge to understand the effects of racism, discrimination, and prejudice — how they impact on our own performance as school psychologists and how they affect every facet of the lives of children in America. The practice of school psychology must be informed by this knowledge and understanding, and NASP supports all efforts, at both a preservice and inservice level, to ensure that this occurs. NASP believes that school psychologists have a critical role to play in making schools culturally sensitive environments. Ultimately, the welfare of all students — and our nation — is at stake.

Adopted by the NASP Delegate Assembly, March, 1993

Rights without Labels

The Rights without Labels concept has been developed to address problems associated with the classification and labeling of children as "handicapped" for educational purposes. This classification establishes certain legal rights for children and parents, often including funds for schools offering specialized services.

Problems permeate this system: unreliability of classification; lack of instructional relevance for some classifications; exclusion of children from regular education; and the stigmatization of classified children. Moreover, removing these classifications and labels to return a student to regular education has proved very difficult.

The Rights without Labels guidelines presented here have special significance for children with academic and/or behavioral difficulties who are frequently classified as learning disabled, educable mentally retarded, or behavioral disordered/emotionally disturbed. Our intention, however, is to apply these guidelines to as broad a range of exceptionalities as is feasible and in no way to diminish opportunities for even the severely/profoundly handicapped student to be served in settings with their non-handicapped peers.

The Rights without Labels guidelines are based on the assumption that it would be desirable at this time to conduct programs wherein efforts are made to serve children who have special needs without labeling them or removing them from regular education programs. Research indicates that several factors are critical to the success of such experimental programs.

Pre-referral Screening/Intervention

Attempts must be made at the very outset to ameliorate educational difficulties through the use of pre-referral screening/intervention methods conducted by regular school personnel with the support of resources typically limited to special education (i.e., school psychologists, teachers, social workers, speech therapists, etc.). This benefits all children, especially those experiencing educational problems, while helping to identify students with characteristics consonant with legal definitions of handicapped conditions. Such practices will engender an abiding respect for students' rights under the law not to be evaluated in the absence of genuine suspicion of a handicap.

Curriculum Based Assessment

Secondly, identification and evaluation methods must include curriculum based assessment procedures. Research demonstrates these procedures provide reliable measures of student performance and produce relevant information for instructional planning. Most importantly, they fulfill the evaluation protection criteria set out in PL 94-142. The primary purpose of these procedures is not to classify or label children, but rather to identify specific curriculum and instructional deficits and strengths in order to provide a framework to develop appropriate educational programs. Individualized Education Programs (IEPs) continue to be required, as well as related services provided in accordance with current legal guidelines.

Special Resources in Regular Settings

The traditional array of special education supplementary aids, services and resources (including teachers/aides) are available to children only outside the regular classroom. Our goal is to broaden the classroom situation within which special education resources can be used and to reverse the practice of moving handicapped students to special education situations outside regular classes and schools. Instead, special education resources can be transferred into the non-categorically identified student's regular classroom setting.

RIGHTS WITHOUT LABELS GUIDELINES

These guidelines are stated positively as principles for programs which professionals, advocates, and parents may wish to examine. The checklist format is provided for use in developing experimental programs in local or state systems.

I. ASSURANCES: Any proposed alternatives non-categorical program or system shall:

  A. Ensure that the fundamental rights afforded handicapped students and their parents under PL 94-142 are maintained and safeguarded. These include, but are not limited to:

    1. Standards for fair and unbiased identification and evaluation of children who would qualify as "handicapped" in a categorical system.

    2. Individualized Education Programs (IEPs) for all students who would otherwise qualify under a categorical system.

    3. Specialized instruction and related services for students who would otherwise qualify under a categorical system.

    4. Least Restrictive Environment (LRE) standards in determining educational placements.

5. Appointment of surrogate parents when appropriate.
6. Non-discriminatory discipline procedures.
7. All timeline standards governing the above practices and procedures.
8. Parental rights in the identification, evaluation, IEPs, and placement of students who would otherwise qualify under a categorical system.
9. Due Process rights for parents and students who wish to pursue concerns/complaints regarding educational evaluations, programs, and placements.
10. Local advisory boards to assist (LEAs) in planning for the provision of appropriate educational services.

B. Provide parents of handicapped students with an alternative to selecting a traditional categorical approach to classification.

C. Provide full disclosure of the non-categorical system to parents including an explanation of resources, services, and rights that will be afforded students in this system.

II. GENERAL QUALITY OF ALTERNATIVE PROGRAM: Any proposed non-categorical program or system shall:

A. Employ pre-referral screening/intervention measures and utilize evaluation procedures that include curriculum-based assessments.

B. Employ methodology known to be associated with effective teaching/learning (for example, provide students with orderly and productive environments, ample learning/teaching time, systematic and objective feedback on performance, well sequenced curricula, etc.).

C. Focus attention on basic skills as priority areas for instruction (for example, language, self-dependence, reasonable social behavior, mathematics, health and safety, etc.).

D. Provide procedures to identify and respond to the individual needs of all students, and in particular, those who may need modifications in their school programs.

E. Provide for special education aids, services, and resources to be delivered in regular education settings.

III. ASSESSMENT OF OUTCOMES: Any proposed non-categorical program shall:

A. Have an objective methodology for assessing the educational progress of students in major curriculum domains (including academic, social, motivational, and attitudinal variables) and for comparing such progress with results in traditional programs.

B. Contain and utilize a cost-benefit analysis to compare costs with traditional programs.

IV. TEACHING STAFF AND FACILITIES: Any proposed non-categorical program shall:

A. Include instruction and services by teachers and staff who are qualified in accordance with current state certification standards.

B. Include a delivery system that provides continuing staff development responsive to the training needs of the teaching staff and administrative personnel who will be implementing the requirements of the non-categorical program.

C. Include appropriate instructional materials and other resources.

D. Include assurances that funding levels and personnel allocations will not be decreased during the experimental period or as a result of successful alternative service delivery.

To provide these assurances it is assumed that as part of the experimental procedures, it would be common to conduct a dual classification system, whereby, for example, a student who might be classified as "learning disabled" in a traditional system would actually be so identified. Although the student's record would reflect the traditional classification, the student would be considered in need of "supplemental services" (ie., regular and special education services) for purposes of his/her participation in the non-categorical program. Only by such a dual system could assurances concerning "rights" be offered and safeguarded. Over the long term, the traditional classification system might be modified if all stakeholders are satisfied with the new procedure.

School Psychologists: Assessment Experts for Restructured Schools

School psychologists have long been recognized for their expertise in developing, conducting, and interpreting individual and program assessment procedures; and

School psychologists are specifically trained in psychometric theory, assessment procedures, and the application of assessment data to educational decisions; and

School psychologists have expertise in norm-referenced assessment techniques that are well grounded in research; and

School psychologists promote the use of technically adequate assessment tools which are directly linked to instruction and intervention; and

Initiatives for school restructuring, such as inclusion, outcome-based education, and site-based management, have significant implications for the evaluation of student and program outcomes; and

New models of schools may require new approaches to student and program evaluation; and

The current empirical base for new approaches such as authentic assessment is very limited; and

Furthermore, be it relayed that the National Association of School Psychologists will work with school psychologists to refine the appropriate use of norm-referenced assessment techniques and expand their understanding and utilization of alternative assessment techniques. NASP will work with training programs to ensure that alternative models of assessment are included in the revision and updating of core curriculum to prepare school psychologists for their roles in restructured schools. NASP affirms its commitment to ensure that practicing school psychologists have opportunities to learn and develop skills in functional and problem-solving assessment through ongoing professional development.

Adopted by the NASP Delegate Assembly, April 17, 1993.

Three Year Evaluations for Handicapped Students

Three-year reevaluation of students in special education placements is a critical assessment concern of school psychologists. Reevaluations are often mechanical, bureaucratic processes which do not address the unique needs of students. Specific problems with current reevaluation practices include excessive emphasis on reestablishing eligibility, rote replication of initial evaluation procedures, excessive reliance on unnecessary psychoeducational tests, and a lack of variation in assessment team membership to reflect the unique concerns of the reevaluation.

Federal law and regulations on reevaluations have been misinterpreted by many state and local school systems. State and local policies often require that the same assessment procedures used for initial evaluation be used for reevaluation and/or that "tests" per se must be administered. In fact, although the same assessment "domains" must be addressed, federal law and regulations allow alternative assessment procedures. Reevaluation practices among professionals vary widely due to these state and local interpretations and to varying understanding of the purposes for conducting the reevaluations. A change in the focus and process of reevaluations as conducted in many places is needed in order to serve the best interests of students and to better utilize time and skills of involved school personnel.

NASP supports, and federal regulations allow, a flexible approach to three-year reevaluations based on the unique needs of the student and the specific questions that need to be answered. Federal guidelines and professional standards call for meaningful, individualized, multifaceted reevaluations which serve the best interests of students. The following factors should be considered in conducting and in shaping the nature of reevaluations.

- The purposes and specific questions for reevaluation should guide the selection of assessment methods. Three broad purposes of reevaluation are:
  1. evaluating the effectiveness of the student's individual education program,
  2. evaluating the appropriateness of the student's current interventions and determining his/her future needs, and
  3. determining whether the student continues to be eligible for special education services.
- Additional factors influence the choice of specific assessment procedures, including the student's age, severity, and nature of handicap(s), progress in school, years in special education, availability of data from many sources (e.g., school and home), and the consistency of the results of previous evaluations.
- Sources of information that may be considered in an assessment include, but are not limited to, review of records, interviews, observations, curriculum-based measures, rating scales, and psychoeducational tests. Some areas of assessment may require procedures from several of these data sources, whereas others may use only one source.
- When any student is placed in a special education program, the ultimate goal whenever feasible should be that student's return to general education. Exit criteria for special programs should include functional assessment of the student's performance in special program/placement options. Criteria written solely in terms of initial eligibility standards do not address the best interest of the child.

In order to implement reevaluation processes that are useful in meeting student and program needs, NASP encourages school psychologists, school administrative units, and state education agencies to develop flexible and meaningful approaches to reevaluation. School psychologists have unique training and expertise in assessment, and their knowledge is crucial in the selection of appropriate, reliable, and valid assessment procedures. They should be available to assist the multidisciplinary team in selecting and conducting assessments which address the efficacy and appropriateness of the student's current program, future program needs, and program eligibility. Of primary importance is the need for school psychologists to assist in developing appropriate instructional strategies in general education settings so that handicapped students may successfully return to the mainstream as soon as possible.

Adopted by the NASP Delegate Assembly, April, 1989.

Student Grade Retention

The National Association of School Psychologists is committed to promoting educational practices that are demonstrably effective in enhancing the educational attainment of all children. The retention of students, while widely practiced, is in large measure not substantiated by sound research.

The cumulative evidence indicates that retention decisions cannot be validated using any standardized or competency-based tests and that retention can negatively affect achievement and social-emotional adjustment.

Retention has not been shown to be successful:

- When it is employed in lieu of other more effective interventions when students fail to learn;
- When it is used to postpone or supplant special education services;
- When it is used at the secondary level where it correlates positively with student drop-out rates;
- When retention or delayed school entrance is used with students with social or behavioral deficits linked to "developmental immaturity."

Retention is least likely to be harmful when students:

- lack serious deficits in the year prior to retention;
- have positive self-esteem and good social skills;
- show signs of difficulty in school because of lack of opportunity for instruction rather than lack of ability;
- do not have serious social, emotional, or behavioral deficits.

Therefore, it is resolved that the National Association of School Psychologists will:

1. Encourage early identification and intervention of academic, behavioral, and/or emotional difficulties to avoid the inappropriate use of retention.
2. Encourage use of interventions other than retention for students in academic difficulty.
3. Promote and publicize research comparing retention to alternative practices at the kindergarten and first grade level with children determined to be at risk for school failure.
4. Encourage school psychologists to assist in the decision-making process about retention of individual students by examining:
   a. the child's school and developmental history.
   b. reasons for school failure (e.g., emotional problems, low ability, frequent school moves or absences).
   c. the effectiveness of instruction (e.g., teaching practices, the match between teaching and learning style and between student achievement level and curricular demands).
   d. the type and quality of alternative strategies (e.g., direct instruction, remedial services, cooperative learning, peer tutoring, etc.).
   e. student attitude toward retention and level of parental support, and
   f. the extent of alternative programming available in both the new and repeated grade.
5. Encourage NASP's state affiliate organizations and individual members to adopt positions and support research which promote alternative interventions to retention.

Approved by the NASP Delegate Assembly, July, 1988.

Appendix VII

A Summary of Credentialing Requirements for School Psychologists in Public School Settings

Joseph Prus
Winthrop University

Michael J. Curtis
University of South Florida

Ashlyn Draper
Winthrop University

Sawyer Hunley
University of Cincinnati

Psychoeducational problem solving and related services provided by psychologists in the schools require substantial breadth and depth of training. School psychologists must be adequately prepared to respond to increasingly diverse and intensive needs of children, youth, and families in a rapidly changing world. Credentialing standards such as certification and licensure requirements are intended to ensure that school psychologists possess minimum qualifications needed to be effective providers of professional services to the public. Requirements for certification or licensure also regulate who may use the title "school psychologist" or legally provide school psychological services, and may affect the level of independent professional functioning and career opportunities available to school psychologists. Thus, familiarity and compliance with the requirements for being certified or licensed are important prerequisites for school psychologists and aspiring school psychologists.

Licensure and certification requirements affect the roles and functions of most educators, health care practitioners, and human service providers, including school psychologists. They are part of the mechanism by which governments and professional regulating bodies protect the health, safety, and welfare of citizens (Council of State Governments, 1952). The existence of credentialing requirements for school psychologists in all 50 states and the District of Columbia as well as certification at the national level thus reflects the perceived importance of our profession in its potential benefit, as well as harm, to members of the public.

There has been a consistent interest in certification and licensure requirements for school psychologists for nearly 50 years (Horrocks, 1946; Clayton, 1950; Hodges, 1960; Gross, Bonham, & Bluestein, 1966; Graff & Clair, 1973; Sewall & Brown, 1976; Brown, Horn, & Lindstrom, 1980; Prus, White, & Pendleton, 1987; Curtis, Hunley, & Prus, 1995). Since its inception, the National Association of School Psychologists (NASP) has been the primary source of review and dissemination of such requirements (Sewall & Brown, 1976; Brown, Horn, & Lindstrom, 1980; Prus, White, & Pendleton, 1987; Curtis, Hunley, & Prus, 1995). In addition, NASP created the National School Psychology Certification System (NSPCS) in 1988 for the purpose of promoting nationally recognized standards for credentialing school psychologists.

In order to qualify to use the designation Nationally Certified School Psychologist, or NCSP, individuals must meet a variety of entry level requirements based on *Standards for the Credentialing of School Psychologists* (NASP, 1994). Requirements include:

- Completion of a sixth year/specialist or higher level degree program in school psychology, with a sixty (60) graduate semester hour minimum consisting of coursework, practica, internship and an appropriate graduate degree from an accredited institution of higher learning;
- Preparation in psychological foundations, educational foundations, assessment, interventions, statistics/research design, and professional school psychology;
- Successful completion of a 1200 hour internship in school psychology, of which 600 hours must be in a school setting. The internship must be supervised by a credentialed school psychologist or a psychologist appropriately credentialed for an alternate setting and be recognized through institutional (transcript) documentation;
- Attainment of a passing score on the National School Psychology Examination administered by Educational Testing Service (ETS/NTE Test #40, which is now part of ETS's PRAXIS series).

As is indicated by the summary of certification and licensure requirements presented later in this chapter, some states have adopted the NCSP credential as a mechanism by which applicants are certified or licensed to practice in the public schools. Others are in the process of considering formal recognition of the NCSP credential in state education regulations.

This chapter presents a summary of certification and licensure requirements for school psychologists in public school settings. It is based on the most recent national review of such requirements completed by NASP in 1994. A risk inherent in any summary is that misinterpretation may occur due to the lack of potentially important details in the summary. The highly detailed information contained in the certificate and licensure regulations of many states, along with ongoing modifications of such regulations, suggest the need for caution in using this summary for professional planning or decision making. The reader interested in the requirements of a particular state should refer to the latest edition of NASP's *Handbook of Certification and Licensure Requirements for School Psychologists* (Curtis, Hunley, & Prus, 1995) or obtain the actual state credentialing requirements (names, addresses, and phone numbers of state contacts are included in the *Handbook*).

Data Collection and Validation

Standardized survey protocols and copies of state credentialing summaries from the Fourth Edition of the *Handbook of Certification and Licensure Requirements for School Psychologists* (Prus, White, & Pendleton, 1987) were mailed to departments of education, certification/licensure offices, and similar departments and offices which oversee state level credentialing for school psychologists. An initial mailing list of state contacts was compiled through the previous edition of NASP's *Handbook*. Phone calls to state offices were conducted in order to update the list prior to mailing.

Respondents were asked to complete the survey, review and revise as needed a written summary of their state standards, and provide copies of administrative codes and statutes for the credentialing of school psychologists in the public schools. Follow-up phone calls and mailings were made to nonrespondents. Ninety-four (94) percent of states responded by completing the survey and reviewing draft summaries of their requirements. Previous summaries, reviews of state regulations obtained through alternate methods, and consultation with state school psychology consultants and trainers were used to summarize the requirements of four states which had not responded to written requests. These states are noted in the summary tables that appear later in this chapter.

Every effort has been made to ensure the presentation of valid summary information regarding certification and licensure requirements. Ultimately, however, the responsibility and authority to provide and interpret credentialing requirements lie with the appropriate agencies within individual states. Consequently, individuals interested in credentialing within a given state should contact the designated official within that state.

Interpretation of Summary Tables

Considerable variation exists in the content and terminology of state credentialing laws and regulations. Most commonly, "licensure" refers to the process of regulation applicable to practice of psychology or school psychology in the private sector or outside the public educational system. The licensure process in this sense is typically administered by state boards of psychology or psychological examiners. "Certification" usually refers to the process of credentialing public school professionals including school psychologists. This process is most often regulated and administered by state departments of education.

The above descriptions of licensure and certification are not universally applicable. For example, some state boards of psychology *certify* psychologists for private practice while some state departments of education refer to their credentialing process as *licensure*. Recent discussions and efforts to promote state *licensure* and national *certification* in education have the potential to add to the confusion regarding these terms. Thus, those seeking credentials are advised to clarify the nature and scope of the credential they desire and the setting in which they plan to work. *Licensure* and *certification* requirements as summarized in this chapter refer to credentials issued by state departments of education and similar agencies and departments for the practice of school psychology in the public schools.

The basic requirements for state credentials for school psychologists in public school settings are summarized in Table 1. This table includes the title and levels of the credential(s) by state, minimum degree and graduate credit hours required, internship and field experience requirements, and whether or not an exam must be passed. It is suggested that the reader review the notes appearing at the end of the table as these define terms and abbreviations used to clarify information in the table.

School psychologists concerned with the "mobility" of their training and credentials should be aware of the processes of credentialing that states utilize for out-of-state applicants wishing to work in the public schools. Some states offer reciprocity, which is a process through which an individual may become credentialed in one state by virtue of possessing a comparable or equivalent credential in another state. Other state departments of education certify or license school psychologists who have completed a training program approved by the state of origin or by an accrediting body or specialty organization such as

NASP. A more recent trend has been the adoption by some states of certification by the National School Psychology Certification Board as a means by which to attain state credentials. State options for school psychology credentialing of out-of-state applicants are summarized in Table 2.

Finally, Table 3 summarizes processes by which in-state applicants are credentialed in school psychology. These processes often differ from the credentialing processes for out-of-state applicants (e.g., a state may require completion of a state-approved training program in school psychology for in-state applicants but accept the NCSP credential or have a reciprocity agreement in granting certification or licensure to those trained in other states). Tables 2 and 3 contain information regarding examination requirements for credentialing school psychologists for work in the public schools.

Wyoming	Educational Diagnostician	Master's	45		2 years (T)	no
	School Psychologist	Doctorate	60	1 year (e)		

NOTES:

Levels and types of certificates that vary in basic training or experience are presented. In some states, additional types of certificates (e.g., a temporary certificate provided to an applicant who lacks one requirement) are available.

Credit hours are given in graduate semester hours unless otherwise designated. "G&U" indicates that a combination of graduate and undergraduate credits may be applied to certification requirements.

In the "Experience" column, "Internship" refers to pre-degree field experience which may be referred to as practica, externships, or internships. Although typically consisting of post-degree experience, the experience listed under the "Field" column may at least in-part include pre-degree experience in some states. An "(e)" indicates that experience can be accepted as an alternative to the internship requirement.

"AP" indicates the existence of a requirement applied to completion of an "approved program".

"C.A.G.S.," Certificate of Advanced Graduate Study, which is typically equivalent to a Specialist degree or Master's plus additional credit hours.

"T" indicates experience that at least partly must be in teaching or its equivalent. In some cases the completion of an approved program or additional coursework is accepted as an alternative to teaching.

"c" indicates experience that must be attained while holding the next "lower" level or type of school psychology certification. For example, Maryland requires 3 years of experience under the level II certificate before awarding the Supervisor of School Psychological Services title.

"*" indicates that the summary of state requirements is based on previous information or on a review of state materials conducted by the authors due to a lack of response on the part of state officials to survey.

NOTES/DEFINITIONS:

"State Approved Program" - Completion of an approved training program in state of origin.

"NASDTEC" - Completion of a program approved via the standards of the National Association of State Directors of Teacher Education and Certification.

"NCATE/NASP" - Completion of a program approved by the National Association of School Psychologists in an institution or unit accredited by the National Council for Accreditation of Teacher Education.

"NCSP" - Attainment of certification from the National School Psychology Certification Board

"Interstate Reciprocity Agreement" - A reciprocity agreement with other states

"Equivalent Training & Certificate" - Documentation of training and certification equivalent to that in the state in which certification is desired.

"Other" - Some other method of review. "APA" refers to completion of a program accredited by the American Psychological Association. An "NA" in this column indicates that, although a process may be in place for certifying in-states applicants, the state reports having no approved school psychology training programs at present.

"Exam" - An examination is required. The designation "NTE" indicates that the School Psychology Specialty Area Test of the National Teachers' Examination (Part of the Praxis Series Professional Assessments for Beginning Teachers administered by the Educational Testing Service) is required or is one option for meeting the exam requirement.

Appendix VIII

A Summary of Licensure Requirements for Independent Practice in Psychology and School Psychology

Joseph Prus
Winthrop University

Kelly Mittelmeier
Winthrop University

Although most school psychologists are employed in public schools, increasing numbers are working in nontraditional settings, including private practice (D'Amato & Dean, 1989; Graden & Curtis, 1991). One reason for this may be the desire for professional role expansion often offered by non-public school settings (Rosenberg & Wonderly, 1990). Another may be increased opportunities for practice in employment settings other than schools due to compromises in psychology licensing acts (Pryzwansky, 1993) and to increased recognition of the expertise and potential contributions of school psychologists. In any case, school psychologists interested in non-public school practice must be familiar with the professional credentials required for such work.

Despite differences from state to state in the terminology and administration of credentials relevant to school psychologists, the process of credentialing psychologists and school psychologists for independent practice is usually called "licensure." Licensure is typically required if psychological services are provided independently to individuals (i.e., "private practice") and may be required for the provision of such services in particular settings (usually exclusive of schools, for which *certification* is usually required). Licensing laws restrict service or practice activity to those professionals holding a certain title or protect professionals in regard to the legitimacy of their offering particular services (Pryzwansky, 1993). As opposed to the credentialing of school psychologists for work in the public schools, which is usually administered by state departments of education or teacher certification divisions or boards, licensure of psychologists is administered by state boards of psychology or psychological examiners.

The purpose of this chapter is to provide a brief summary of the licensure requirements for independent practice in psychology and school psychology. Those interested in more in-depth discussions of licensure and its applications to school psychology are encouraged to read Prasse (1988) and Pryzwansky (1993). Batsche (1990), Batsche, Knoff, and Peterson (1989), Fagan and Wise (1994), and Pryzwansky (1993) also provide useful recent overviews of school psychology credentialing.

Sources of Information on State Licensure Requirements

Although the National Association of School Psychologists (NASP) has since its inception been the primary source of review and dissemination of state credentialing requirements for school psychologists (Sewall & Brown, 1976; Brown, Horn, & Lindstrom, 1980; Prus, White, & Pendleton, 1987; Curtis, Hunley, & Prus, 1995), licensure requirements for the independent practice of psychology have been influenced and more closely monitored by the American Psychological Association (APA) and the Association of State and Provincial Psychology Boards (ASPPB). The ASPPB conducts an annual update of licensure/certification requirements for psychologists in North America.

The summary of licensure requirements for the independent practice of psychology and school psychology presented in this chapter was prepared by using ASPPB's *Handbook of Licensing and Certification Requirements for Psychologists in North America* (1994) to update and supplement information contained in NASP's *Handbook of Certification and Licensure Requirements for School Psychologists* (Prus, White, & Pendleton, 1987). The resulting product should be a useful general guide to state licensure requirements. However, readers interested in a more in-depth, state-by-state description of licensure requirements and other information and materials related to licensure are encouraged to contact ASPPB (P.O. Box 4389, Montgomery, Alabama 36103).

Interpretation of Licensure Information

Table 1 contains a state-by-state summary of psychology licensure requirements. As is evident in the information presented in the table, considerable variation exists from state to state in the terminology and requirements pertinent to licensure by state psychology boards. This variability makes the tabular presentation of data somewhat of a challenge. The condensing of information into table format, while useful for purposes of comparison and summarizing, required the elimination of details that may be relevant to individuals seeking licensure. Thus, readers interested in the licensure requirements of a particular state are strongly advised to contact the state board of psychology or psychological examiners in that state to obtain complete, valid information.

In interpreting the information in Table 1, blank spaces signify the lack of a specified requirement. Since the statutes in many states grant licensure boards some or considerable autonomy in administering requirements, however, the lack of a specified requirement may mean that either no requirement exists or that the details are left to the discretion of the state board. The following descriptions of each heading are provided as aids to the interpretation of Table 1.

Title: Psychologists credentialed to provide independent or private services to the public may be described by a number of different titles, including "psychologist," "licensed psychologist," or "certified psychologist." Terms such as "clinical psychologist" or "health services provider" may be used to describe psychologists in applied specialties such as clinical, counseling, or school psychology who provide health-related or clinical services. In such cases, licensure as a psychologist may be a prerequisite to a clinical psychologist or health service provider credential. Some states also offer licensure specifically as a "school psychologist." Others recognize a variety of specialties, including school psychology, but issue licensure under one title such as "psychologist."

Minimum Degree: The minimum degree required for each credential is listed in the third column of the table. Although the degree requirements are summarized as "Masters" or "Doctorate," states often specify the particular degrees (e.g., Ph.D., Ed.D., Psy.D.) and fields of study required. Twenty-five states now have provisions for licensure at the masters degree or equivalent level. Such credentials typically include restrictions of function and/or supervision requirements.

Experience: The experience required for each licensure is summarized in three columns as described below.

Post-Degree: The number of years or hours of experience acquired after a degree is awarded.

Supervised: The number of years or hours of supervised experience. Most states further specify the required amount and/or conditions of supervision.

Total: The total number of years or hours of experience required for license.

In cases where states require a minimum number of years *and* hours of experience, only years are reported in the table.

It may be helpful to read the "Experience" columns in the table from right to left. For example, Alabama requires one year of experience, all of which must be supervised, whereas Florida requires 4000 hours of experience, 2000 hours of which must be post-degree and 4000 hours of which must be supervised.

Mandatory Exam: All states require at least one examination for licensure and most require both national and state exams. The Examination for the Professional Practice of Psychology (EPPP) is required by all states for at least one type or level of license. Some states that offer a school psychologist licensure require the School Psychology examination of the National Teachers Examination (NTE) for such licensure. Where a "board exam" is required, the examination may include an oral exam, written exam, or both. The designation "Must be Licensed" in the table indicates that an examination is required by virtue of having another type of licensure as a prerequisite.

Continuing Education Requirement: Most states require a minimum number of continuing education hours for licensure renewal. The required hours, "credits," or "CEUs" for each renewal period are listed in the far right column of Table 1. Renewal periods vary from state to state. For example, Arkansas requires completion of 20 hours of continuing education every year whereas Oregon requires 50 hours every two years. "Hours," "credits," or "CEUs" typically refer to hours or contact hours in approved continuing education activities.

ACKNOWLEDGMENTS

The authors are grateful to the Association of State and Provincial Psychology Boards for making available the information that served as a basis for this summary.

Resources on the Training of School Psychologists

Douglas K. Smith
University of Wisconsin–River Falls

Thomas K. Fagan
Memphis State University

Published listings of programs specifically for the preparation of school psychologists date to at least the early 1940s when, in an official publication, the New York State Education Department identified several programs. Perhaps the first nationwide listing was that appearing in the Thayer Conference proceedings published in 1955. Since the 1960s, articles have been regularly published on the growth of training programs. Though these studies identified the program institutions, they often conveyed little information about program philosophy, goals, content, and characteristics. A summary of these studies indicated that the number of institutions offering one or more levels of training grew from about 28 in the 1950s to more than 100 by 1970 and more than 200 by the 1980s (Fagan, 1986). There are now about seven times as many training institutions as existed in 1960.

NASP published the results of its first survey of training programs in 1972 (Patros, et al., 1972). The pamphlet identified 153 United States and 4 Canadian training institutions and included information about degree levels and financial assistance. The first formal directory of training programs was published by NASP in 1977 (Brown & Lindstrom, 1977), with two subsequent revisions (Brown & Minke, 1984; McMaster, Reschly, & Peters, 1989). The original 1977 directory identified 203 United States and 17 Canadian institutions; subsequent revisions have included U.S. institutions only. The 1984 revision described 210 institutions, and the 1989 *Directory* revision identified 203 institutions which provided information on their programs and 28 which failed to respond. The NASP directories have included increasingly greater information about the characteristics of preparation programs. The directories serve as the only national listing of preparation programs exclusively in school psychology. The most recent *Directory* revision (Smith & Henning, in press) is the most comprehensive resource of school psychology program information. It identifies 212 training institutions, which suggests a pattern of stability since the mid-1980s, and provides detailed information on the 208 programs responding to the directory survey.

Other resources have been available to assist prospective students in identifying training programs and/or in making a career decision to enter the field of school psychology. These include: the American Psychological Association's *Graduate Programs in Psychology*, an annual publication which includes departmental information on each type of graduate program' accreditation listings and information available from APA and NCATE/NASP; and several published items related to training (Curtis & Zins, 1989; Fagan, 1990; Gerner & Genshaft, 1981; Knoff, 1986; National School Psychology Inservice Training Network, 1984).

The data tables in this appendix are drawn from a 1993 NASP survey which appears in the 1994 NASP directory (Smith & Henning, 1994) and represent information based on the 1992–1993 year. This appendix provides a tabular summary of that survey related to the following data:

a. An alphabetical list, by states, of programs including name, address, phone, contact person, degrees offered, and NASP accreditation status.

b. A NASP regional listing of programs by name only, organized alphabetically by state and program name.

c. Maps of the United States identifying the location of masters, specialist, and doctoral programs.

The appendix serves as a resource of program information for prospective and current students, and for persons researching the status and history of school psychology training.

ANNOTATED BIBLIOGRAPHY

Brown, D. T., & Minke, K. M. (1986). School psychology graduate training: A comprehensive analysis. *American Psychologist, 41,* 1328–1338.
From both historical and contemporary perspectives, the authors describe the decline in master's level programs with attendant increases in specialist and doctoral programs. It is estimated that half the graduate students in school psychology will be enrolled in doctoral programs by 1990. The content analyses of specialist and doctoral programs suggest the practical proximity of the specialist to the doctorate and the need for greater job opportunities for some programs to acquire the doctoral status. Implications for the issues of entry-level titles and credentials are presented.

Curtis, M. J., & Zins, J. E. (1989). Trends in training and accreditation. *School Psychology Review, 18,* 182–192.
Written as part of the "NASP at Twenty" mini-series, this article chronicles the growth of school psychology and training during NASP's first twenty years. A strong trend is identified for practitioners and students to acquire increased levels of preparation with the specialist and doctoral levels showing considerable growth. The influence of NASP in the development of training standards, especially for nondoctoral programs, is emphasized. NASP's accreditation relationship to NCATE is also discussed. Future challenges identified included personnel shortages, the need for greater minority student enrollments, quality assurance through NCATE accreditation mechanisms, and standards revisions. The specialist level standards are perceived as inadequate to meet future needs for alternative school psychological services. Expansion and revision of these standards will be needed, and perhaps two or more levels of practice will emerge in the future.

Fagan, T. K. (1986). The historical origins and growth of programs to prepare school psychologists in the United States. *Journal of School Psychology, 24,* 9–22.
A survey of the quantitative growth of school psychology training programs across the twentieth century. Identifies the earliest training institutions and the scarcity of such institutions prior to the 1960s. A tabular summary of published studies indicates the growth of program institutions from 28 in 1954, to 79 in 1964, to 147 in 1974, and 211 in 1984. Information regarding training content and enrollments are also provided.

National School Psychology Inservice Training Network. (1984). *School psychology: A blueprint for training and practice.* Minneapolis, MN: Author.
Employing the *Nation At Risk* study published in 1983, this publication identifies several problematic areas of education and special education and their relationship to school psychological services. Following a reconceptualization of the functions of the school psychologist, the report identifies several areas of needed training and retraining for the future. The reconceptualization is along lines of consultation, and curriculum-based assessment, while disbanding functions associated with classification in the categories of learning disabled, educably mentally retarded, and behavior disordered or emotionally disturbed.

Reschly, D. J., & McMaster-Beyer, M. (1991). Influence of degree level, institutional orientation, college affiliation, and accreditation status on school psychology graduate education. *Professional Psychology: Research and Practice, 22,* 368–374.
Based on survey responses associated with the 1989 NASP *Directory of School Psychology Graduate Programs*, comparisons are made among programs based on program levels, institutional orientation, academic department (e.g., education vs. arts and sciences), and type of accreditation. After alerting the reader to the study's limitations, the authors contend that the specialist and doctoral level data support the "long-standing APA policy that restricts the independent, unsupervised practice of psychology in varied settings to doctoral-level professional psychologists" (p. 373). The authors also interpreted the data to favor research oriented institutions, though differences associated with academic location and accreditation were not observed.

---

[1] This Table contains a program listing by state. The listing indicates the name of the university, address, phone number, name of the program director, degree(s) offered, and NASP accreditation status. This information is current as of December 30, 1994. NASP accreditation status is on a voluntary basis and some programs have not been reviewed. Thus, it cannot be assumed that a program does not meet national training standards because it is not included as having NASP accreditation. Compliance with national standards should be verified directly with the program (Program Level: SL = Specialist Level and DL = Doctoral Level).

TABLE 2
Regional Listing of School Psychology Programs

NORTHEASTERN REGION

Connecticut

Fairfield University, Fairfield, CT
Southern Connecticut University, New Haven, CT
University of Connecticut, Storrs, CT
University of Hartford, West Hartford, CT

Delaware

University of Delaware, Newark, DE

Maine

University of Southern Maine, Gorham, ME

Massachusetts

American International College, Springfield, MA
Northeastern University, Boston, MA
Tufts University, Boston, MA
University of Massachusetts–Amherst, Amherst, MA
University of Massachusetts–Boston, Boston, MA

New Jersey

Jersey City State College, Jersey City, NJ
Kean College of New Jersey, Union, NJ
Montclair State College, Upper Montclair, NJ
Rider College, Lawrenceville, NJ
Rowan College of New Jersey, Glassboro, NJ
Rutgers University, Piscataway, NJ
Seton Hall University, South Orange, NJ

New York

Alfred University, Alfred, NY
Brooklyn College of the City University Brooklyn, NY
City University of New York–City College, New York, NY
College of New Rochelle, New Rochelle, NY
Fordham University–Lincoln Center, New York, NY
Hofstra University, Hempstead, NY
New York University, New York, NY
Pace University, New York, NY
Queens College, City University of New York, Flushing, NY
Rochester Institute of Technology, Rochester, NY
St. John's University, Jamica, NY
State University College–Plattsburgh, Plattsburgh, NY
State University of New York–Albany, Albany, NY
State University of New York–Buffalo, Buffalo, NY
State University of New York–Oswego, Oswego, NY
Syracuse University, Syracuse, NY
Teachers College, Columbia University, New York, NY
Yeshiva University, Bronx, NY

Pennsylvania

Bryn Mawr College, Bryn Mawr, PA
Bucknell University, Lewisburg, PA
California University of Pennsylvania, California, PA
Duquesne University, Pittsburgh, PA
Edinboro University of Pennsylvania, Edinboro, PA
Immaculata College, Immaculata, PA
Indiana University of Pennsylvania, Indiana, PA
Lehigh University, Bethlehem, PA
Marywood College, Scranton, PA
Millersville University of Pennsylvania, Millersville, PA
Pennsylvania State University, University Park, PA
Temple University, Philadelphia, PA
University of Pennsylvania, Philadelphia, PA

Rhode Island

Rhode Island College, Providence, RI
University of Rhode Island, Kingston, RI

SOUTHEASTERN REGION

Alabama

Alabama A & M University, Normal, AL
Auburn University, Auburn, AL
The University of Alabama, Tuscaloosa, AL
University of Alabama–Birmingham, Birmingham, AL

Florida

Florida A & M University, Tallahassee, FL
Florida International University, Miami, FL
Florida State University, Tallahassee, FL
University of Central Florida, Orlando, FL
University of Florida, Gainesville, FL
University of South Florida, Tampa, FL
University of West Florida, Pensacola, FL

Georgia

Georgia Southern University, Statesboro, GA
Georgia State University, Atlanta, GA
University of Georgia, Athens, GA
Valdosta State University, Valdosta, GA

Kentucky

Eastern Kentucky University, Richmond, KY
University of Kentucky, Lexington, KY
Western Kentucky University, Bowling Green, KY

Maryland

Towson State University, Towson, MD
University of Maryland, College Park, MD

Mississippi

University of Southern Mississippi, Hattiesburg, MS

North Carolina

Appalachian State University, Boone, NC
East Carolina University, Greenville, NC
North Carolina State University, Raleigh, NC
University of North Carolina–Chapel Hill, Chapel Hill, NC
Western Carolina University, Cullowhee, NC

South Carolina

The Citadel, Charleston, SC
University of South Carolina, Columbia, SC
Winthrop University, Rock Hill, SC

Tennessee

Austin Peay State University, Clarksville, TN
Middle Tennessee State University, Murfreesboro, TN
Tennessee State University, Nashville, TN
Tennessee Technological University, Cokesville, TN
The University of Memphis, Memphis, TN

University of Tennessee–Chattanooga, Chattanooga, TN
University of Tennessee–Knoxville, Knoxville, TN

Virginia

College of William and Mary, Williamsburg, VA
George Mason University, Fairfax, VA
James Madison University, Harrisonburg, VA
Radford University, Radford, VA
University of Virginia, Charlottesville, VA

District of Columbia

Gallaudet University, Washington, DC
Howard University, Washington, DC

West Virginia

West Virginia Graduate College, Institute, WV

NORTH CENTRAL REGION

Illinois

Eastern Illinois University, Charleston, IL
Governors State University, University Park, IL
Illinois State University, Normal, IL
Loyola University of Chicago, Chicago, IL
National-Louis University, Evanston, IL
Northern Illinois University, DeKalb, IL
Southern Illinois University–Edwardsville, Edwardsville, IL
Western Illinois University, Macomb, IL

Indiana

Ball State University, Muncie, IN
Indiana State University, Terre Haute, IN
Indiana University, Bloomington, IN
Valparaiso University, Valparaiso, IN

Michigan

Andrews University, Berrien Springs, MI
Central Michigan University, Mt. Pleasant, MI
Eastern Michigan University, Ypsilanti, MI
Michigan State University, East Lansing, MI
University of Detroit–Mercy, Detroit, MI
Wayne State University, Detroit, MI
Western Michigan University, Kalamazoo, MI

Ohio

Bowling Green State University, Bowling Green, OH
Cleveland State University, Cleveland, OH
John Carroll University, University Heights, OH
Kent State University, Kent, OH
Miami University, Oxford, OH
Ohio State University, Columbus, OH
University of Akron, Akron, OH
University of Cincinnati, Cincinnati, OH
University of Dayton, Dayton, OH
University of Toledo, Toledo, OH

Wisconsin

Marquette University, Milwaukee, WI
University of Wisconsin–Eau Claire, Eau Claire, WI
University of Wisconsin–La Crosse, La Crosse, WI
University of Wisconsin–Madison, Madison, WI
University of Wisconsin–Milwaukee, Milwaukee, WI
University of Wisconson–River Falls, River Falls, WI

Medications Commonly Used to Treat Children and Adolescents with Convulsive Disorders, Juvenile Rheumatoid Arthritis and Respiratory Illnesses

Susan Vess
University of Southern Maine

OVERVIEW

School psychologists encounter children and adilescents with health problems who take prescribed medication. Their problems and the medications used to treat them may hinder or change the child's or adolescent's academic performance, behavior, and social interactions. Therefore, it is reasonable that school psychologists know how medications work in general, basic information about categories of medications, and preliminary facts about specific drugs.

BASIC CONSIDERATIONS

Drugs are chemicals which produce a variety of effects on the body as they circulate through the blood stream. No drug is completely safe. Every drug has desired effects, meaning it treats the symptoms or disorder for which it was prescribed and also produces undesired effects. Every drug has multiple effects so one person's desired effect is someone else's undesired effect. Individual drugs vary in degree and type of therapeutic effects and negative reactions. Their influence on the organs of the body accounts for both desired and undesired effects. Drugs never act as bullets speeding to the precise site where a desired action will occur.

When prescribing medication, it is important to wiegh the potential benefits of the drug against its negative effects. Additionally, the patient must be told about the benefits and possible risks of a drug, alternative treatments, and the implications of no treatment.

Some body systems are immature until adolescence, while others are adultlike in childhood (Bindler, Tso, & Howry, 1986; Pagliaro & Pagliaro, 1986). The maturity of a particular organ influences the speed with which the drug is absorbed, distributed, achieves its desired effect, or is excreted (Bindler, Tso, & Howry, 1986). Thus, the general principles of pharmacology and pharmakinetics (study of the processes of absorption, distribution, and excretion of drugs) apply to children and adults (Malseed & Harrigan, 1989).

Calculations using rules taking into account a child's age, height, weight, and/or body surface area are used to select dosage (Pagliaro & Pagliaro, 1986). Each method suggests a slightly different pediatric dose. Adult dosages are exceeded if the drug specifically requires a greater amount to treat children effectively.

Although age may be used to estimate the child's developmental level, the size of the child is an important factor. Small children may be overmedicated and large children undermedicated when dosage level is based on age alone. Surface area of the body is the preferred means of establishing dosage because this metric provides the best information about the efficiency of the child's metabolism, the amount of blood and other fluids, and the effectiveness of the kidneys in ridding the body of waste (Bindler, Tso, & Howry, 1986).

Other factors also contribute to difficulty in predicting and recommending pediatric dosages (Malseed & Harrigan, 1989). There are few controlled studies of drugs with children because of the relatively small numbers treated with any drug and the expense of this kind of research. Additionally, the potential for short-term side effects and negative long-term consequences of drug treatment of children ethically and practically limits the use of medication.

Depending on their ages, children tolerate drugs differently (Bindler & Howry, 1991). Moreover, the therapeutic dosage level and effect of a drug given to children may differ from those of adults. Generally, treatment of children begins with the lowest effective dosage and then the amount is increased as tolerance for the drug increases or a higher dosage is necessary to achieve therapeutic efficacy. However, side effects may occur in children at lower doses than with adults. Further, unique effects such as stained teeth from tetracyclines and growth suppression from corticosteroids are found with children (Friesen, 1987).

Compliance

Compliance or treatment adherence is defined as the ability and willingness to subscribe to recommended medication, including the number of doses and duration of therapy (Feist & Brannon, 1988; Reiss & Melick, 1987). It presumes that the condition is accurately diagnosed and treatable and that the physician selects an appropriate medication. It is also assumed that the drug is taken at a therapeutic level and the use of multiple drugs has not altered the effectiveness of any medication. Compliance with treatment does not assume either symptomatic relief or cure of the condition.

La Greca (1988) concluded from her review of the literature that a significant percentage of children and their caregivers fail to comply with treatments of acute ailments, such as otitis media and upper respiratory infections (URIs) and chronic disorders, such as epilepsy and asthma. Mothers are only as compliant with their children's treatments as they are with their own (Feist & Brannon, 1988). The overall predicted rate of compliance for children and adults approximates 50% (Feist & Brannon, 1988; La Greca, 1988). It is not possible to predict who will and will not comply with prescribed treatment.

Generally, people adhere to treatments when there is an immediate reduction in symptoms or relief from pain. With acute illnesses, they often discontinue medication when symptoms abate. Other manifestations of noncompliance include taking less medicine than prescribed, taking more medicine than prescribed in the hope of achieving a quicker or more effective response, doubling up on doses to make up for a missed dose, and hoarding drugs to treat a similar condition in the future.

People fail to comply with prescribed treatment for a variety of reasons, including inadequate understanding of the disorder or the medication, dissatisfaction with the doctor, cost of medication, annoying side effects, rejection of the diagnosis, or belief that taking medication is a sign of personal weakness. An additional concern is fear of addiction and dependence.

Regardless of the illness, chronicity is associated with poorer compliance (La Greca, 1988). Compliance is jeopardized when the treatment alters the person's life style, is prescribed for an extended period, includes multiple drugs, involves different schedules of administration or multiple medications, and/or works by preventing the appearance of the disorder/symptoms (Feist & Brannon, 1988; La Greca, 1988).

Side Effects

Side effects are the result of exaggerated pharmacological action of the drug in which the patient is drug toxic either from acute overdose or from accumulation of the drug in the body (Spunt, Hermann, & Rousseau, 1986). They are usually annoying, mild, and unavoidable (Malseed & Harrigan, 1989). Most side effects are well-known and are attributed to the pharmacological properties of the drug. Evaluating patients for side effects includes their subjective report and monitoring with objective measures such as serum concentrations.

Some drugs produce adverse reactions which are toxicities from high concentrations of the drug in the body. These negative effects involve severe reactions involving multiple systems in the body and may be unexpected. Adverse reactions include addiction, allergic reactions, anaphylactic shock, convulsions, hearing impairment, photosensitivity, psychosis, and respiratory depression (Malseed & Harrigan, 1989).

Some drugs produce non-dose dependent idiosyncratic reactions. These reactions are drug allergies in which histamines produce allergic symptoms from skin rashes to fatal toxicities. Non-dose dependent adverse effects include over or under responsiveness to the drug, abnormal tolerance, or a qualitatively different effect such as excitation with a sedative (Malseed & Harrigan, 1989; Spunt, Hermann, & Rousseau, 1986). Symptoms range from mild to severe and from local to widespread and appear immediately to days after administration of the drug.

When an idiosyncratic reaction occurs, the drug is discontinued immediately and is unlikely to be tried again. The patient is described as allergic only in the case of an idiosyncratic response to a drug. To confuse or label annoying side effects as signs of an allergy may mean that a safe, effective drug is not tried again.

Polypharmacy, the administration of multiple drugs to the same person, is usually avoided. However, advantageous administration of multiple drugs is designed to improve symptoms better than any drug achieves alone. The number of possible negative effects increases greatly as drugs are added to treatment (Malseed & Harrigan, 1989). This may result in drug interactions, side effects where the action of one drug influences or negates the action of another.

Of particular concern with children and adolescents are problems such as treating them with distasteful medications or with painful or frightening routes of administration, teaching them about their disorder and its treatment, and helping them develop ownership of their treatment. Pagliaro and Pagliaro (1986) identified the following ways of misadministering drugs to children: (a) choosing a drug that requires multiple doses when single dose drugs are available, (b) giving drugs with important foods because of the risk of associating food with an unpleasant medicinal taste, and (c) making drugs tasty or equating them with candy. Treating children and adolescents with drugs requires understanding of treatment, recognizing desired and negative effects of a particular drug, patience, finesse, and recognition of the child's level of development.

Seizure Disorders

Epilepsy is a group of central nervous system (CNS) seizure disorders that are manifestations of abnormal electrical activity in the brain, especially the cerebral cortex. Each seizure type has a characteristic electroencephalogram (EEG) and symptom pattern. The electrical activity is usually episodic and may occur spontaneously or may be triggered by stimuli such as stress, fever and illness, hyperventilation, photosensitivity, poor nutrition, and hormonal imbalances.

Status epilepticus is an exception in which multiple generalized convulsions continue without interruption or return to consciousness or normal muscle tone. Status epilepticus is dangerous, even life threatening, because of impaired respiration or lack of oxygen getting to the brain.

When seizures are secondary to another medical condition, their treatment involves resolving the underlying disorder. Seizures not secondary to another disorder are treated with anticonvulsants. These chemically diverse drugs depress abnormal neuronal discharges in the CNS. Anticonvulsants differ in how they control seizures and what kinds of seizures they treat.

Side effects of anticonvulsants are expected because of their long-term use, their relatively high doses, and their frequent combination (Spunt, Hermann, & Rousseau, 1986). They are classified according to three criteria: (a) intoxification from high concentrations in the blood, (b) common side effects associated with therapeutic dosages, and (c) idiosyncratic reactions (Gadow, 1986). It is always important to monitor the achievement and behavior of children taking anticonvulsants.

Although chronic seizure activity has been associated with problems in learning, behavior, and mood, anticonvulsants are not recommended to treat childhood behavior disorders (Biederman & Steingard, 1991). Nevertheless, Dilantin and Tegretol have been used to treat aggression, impulsivity, and restlessness even in the absence of seizures (Biederman & Steingard, 1991).

Arthritic Conditions

Arthritis is a disease of the joints which occurs in over 100 forms, especially osteoarthritis and rheumatoid arthritis (RA). Arthritis is characterized by inflammation in the joints, surrounding tissues, or both. Inflammation is indicated by redness, swelling, warmth to the touch, and tenderness (Phillips, 1988). Because of this inflammation, the patient experiences pain, stiffness, and reduced mobility (Phillips, 1988).

There are several different forms of arthritis in children, but the most common is Juvenile Rheumatoid Arthritis (JRA). Approximately 250,000 children have JRA (DHHS, 1991). The major symptom of JRA is inflammation of the joints which may have a negative effect on bone growth and physical development during active phases of the disease.

Arthritis is neither preventable nor curable. The treament of adult and child forms of arthritis is very similar and shares goals including relief of symptoms such as inflammation, pain and fever, and maintenance or restoration of functioning of the joints. To achieve these objectives, drugs are combined with good nutrition and physical therapy.

Antiarthritis drugs demonstrate one or more of the following effects: (a) antiinflammatory, (b) antipyretic in the presence of fever, (c) analgesic, and (d) anti-coagulant. Generally, medication is required for several months to years with the primary goals of reducing inflammation and pain and allowing greater mobility. Over the long term, drugs may alter the progress of the arthritis and halt destruction of bones and soft tissues.

Nonsteroidal and Antiinflammatory Drugs (NSAIDs) such as aspirin and other salicylates and medications including ibuprofen are the first tried in the treatment of arthritic symptoms. Most of the drugs used to treat arthritis require weeks to months for treatment effects to become apparent. These nonnarcotic analgesics relieve the fever of arthritis within hours, although several weeks may be needed to control the high fevers of JRA. Relief of pain and stiffness occurs next and then reduction in swelling and inflammation follows several weeks of treatment. Improvement in these symptoms of arthritis is accompanied by improved mobility.

NSAIDs without salicylates are similiar to aspirin in effectiveness in relieving the symptoms of RA, but require a prescription and produce somewhat different side effects. Some are also used as analgesics and antipyretics to treat dental extractions, athletic injuries, and dysmenorrhea. NSAIDs without salicylates became more important in the treament of JRA when the connection between aspirin and Reye's syndrome became apparent. Reye's syndrome rarely occurs now in either the United States or in countries that continued to use aspirin (Brewer & Angel, 1992).

There are 15 NSAIDs on the market (DHHS, 1991). Brewer and Angel (1992) estimated that the first NSAID prescribed for a particular patient has only a 50% chance of being effective and reported that several drugs are tried before the most effective medication is identified. NSAIDs approved for use with children include aspirin, Advil, Motrin, Nuprin, Naprosyn, and Tolectin.

NSAIDs are rarely used or studied with children, but may be safely prescribed because no NSAID has been found more toxic with children than with adults (Brewer & Angel, 1992). No NSAID is more effective or more toxic than another, but each is somewhat more or less effective with a particular individual. NSAIDs are similar in pain relief, but differ in side effects (NIA, 1990). Common side effects include stomach pain and cramps, nausea, heartburn, vomiting, diarrhea, and constipation. Fewer than 5% of children experience side effects from NSAIDs that are sufficiently severe to stop treatment (Brewer & Angel, 1992). Non-aspirin NSAIDs produce anemia in 2 to 3 percent of children (Brewer & Angel, 1992). Aspirin affects one-sixth of children and damages liver functioning in 10% of children (Brewer & Angel, 1992).

Second-line drugs, including disease modifiers, immunosuppressants, and corticosteroids are used to treat arthritis when NSAIDs are inadequate in the reduction of pain and inflammation. They are used when drastic measures are needed to treat stiff, painful, or damaged joints, when other joints and organs are affected, when fatigue increases and is prolonged, or when low grade fevers persist (Phillips, 1988). These drugs take months to achieve their effects so are called slower-acting anti-rheumatic drugs (Brewer & Angel, 1992).

Disease modifiers, including gold, d-penicillamine and antimalarial agents are used to treat RA when the patient has experienced symptoms for at least six months without relief from NSAIDs (DHHS, 1991). Although not useful for osteoarthritis, these drugs slow the progress of RA.

RA is an autoimmune disease. Hence, drugs which suppress the immune system relieve the symptoms of RA and JRA. Immunosuppressants include methotrexate, the anti-cancer (cytotoxic) drugs and steroids. Cytotoxic drugs used to treat arthritis include Imuran (azathioprine), Cytoxan (cyclophosomide), and Leukeran (cholorambucil). In serious incapacitating cases of JRA, steroids rapidly control high fever, severe pain, and joint swelling and reduce inflammation in the eyes and around the heart (Brewer & Angel, 1992).

Immunosuppressant drugs are used in the treatment of RA when other drugs do not work, the RA is so severe that other organs of the body such as the eyes and heart are involved, or when the child is at risk of death or loss of sight (Brewer & Angel, 1992). By suppressing the body's immune system, these drugs reduce the body's overall effectiveness in resisting infections and may mask symptoms such as fever and pain which are diagnostically important and common to both infections and arthritis.

Allergic Reactions

Allergies are immune system dysfunctons in which there is an exaggerated response to substances, called allergens, to which most people show no reaction. These allergies enter the body through inhalation (pollen, dust, mold, and pet dander), ingestion (milk, eggs, wheat, shrimp, peanuts and other nuts), injection (penicillin and other shots and insect bites), and absorption through the skin (poison ivy, sumac, poison oak, cosmetics, and othe plant and environmental substances) (Lockey, Fox, & Ledford, nd). The most common allergic disorders include: (a) allergic rhinitis (hay fever) with symptoms such as nasal stuffiness and itching, repeated and often violent sneezing, clear nasal discharge, red, runny eyes, and itching of the ears or roof of the mouth; (b) allergic asthma with symptoms such as wheezing, coughing, and shortness of breath; (c) allergic conjunctivitis with symptoms such as red, itchy eyes with a mucus-related discharge; (d) allergic eczema or skin rash; and (e) allergic contact dermatitis caused by poison ivy, deodorants, dyes, metals, and other allergens (Lockey, Fox, & Ledford, nd). Allergic skin reactions include atopic dermatitis/eczema, hives, and contact dermatitis (Steinmann, 1992). They may also include angioma, a swelling of the underlying tissues of the body. In skin allergies, this swelling usually involves the eyes, lips, and ears.

Anaphylaxis is the term used to describe any severe, body wide allergic reaction to food, drugs, and the venom of stinging insects. It occurs most often with antibiotics, especially penicillin, but may not be caused by the drug itself as much as a constituent part such as eggs or horse serum. Allergies rarely cause anaphylaxis. In anaphylaxis, the tissues of the airways swell which may threaten life. It is indicated by an extreme drop in blood pressure and body temperature, irregular heartbeat, palpitations, flushing, itching, throbbing in the ears, swelling, coughing, sneezing, and difficulty breathing. The person may become unconscious and go into shock.

Antihistamines prevent the release of and block the action of histamines which cause allergic reactions. Hence, they are most effective when taken at the first appearance of symptoms and only provide relief as long as they are taken (Clayton & Stock, 1993). They are most often prescribed to relieve the symptoms of allergies such as allergic and seasonal rhinitis, urticaria (hives), and conjunctivitis. Antihistamines treat allergies by drying up secretions in the nose, throat, and broncial tree.

Antihistamines are not part of the treatment of the comon cold or viruses because they are not caused by histamines. However, because antihistamines produce mild anticholinergic effects including reduction of mucus secretions, they may be used to provide symptomatic relief of colds. Due to their anticholinergic effects on the respiratory tract, they re not used in the treatment of children with asthma unless they also have nasal and skin allergies. Antihistamines work in about 30 minutes to relieve itching, sneezing, watery eyes, runny nose, and other symptoms of allergies.

Decongestants purchased over the counter (OTC) or by prescription control the symptoms of allergies and asthma, prevent acute attacks of these disorders, and reduce or even prevent inflammation. They also treat colds, acute and chronic inflammations, hay fever, and middle ear infections. Tolerance develops rapidly to decongestants and a rebound effect may occur.

Nasal decongestants temporarily relieve nasal stuffiness, inflammation, and sinus congestion due to the common cold, alergic rhinitis, hay fever, and other acute and seasonal disorders (Julien, 1988). They are used to reduce nasal congestion or discharge from increased secretion in the nose (Steinmann, 1992; Bindler, Tso, & Howry, 1991). Decongestants are structurally related to amphetamines, but differ in their impact on heart rate, breathing, and the degree of stimulation produced (Julien, 1992). Because these drugs are stimulants, the child may become more active for several hours after taking the drug and experience insomnia (Steinmann, 1992).

Coughing is the body's natural protective action to expel foreign particles from its respiratory tract (Julien, 1988). It may also be a reflex response to irritation, inflammation, and thick or accumulated secretions (Malseed & Harrigan, 1989; Julien, 1988). However, in a nonproductive cough, the coughing reflex is triggered, but the irritant is not eliminated. Continued nonproductive coughing irritates the respiratory tract and perpetuates coughing (Clayton & Stock, 1993).

Antitussives include both narcotic and nonnarcotic drugs that relieve dry, unproductive coughing through suppression of the cough reflex. They do not completely eliminate coughing, but provide enough relief to enable the person to carry on routine activities or sleep.

Coughs that are productive in expelling excess mucus from the respiratory tract are allowed to continue. Expectorates are drugs that increase mucus formation, liquefy thickened bronchial secretions and stimulate their flow (Julien, 1988). They are used to treat obstructive pulmonary diseases such as asthma, chronic bronchitis, and emphysema and to reduce dry irritating coughs of the common cold. Glyceryl guaiacolate is the most widely used drug in expectorates and is found in common cough medicines.

Upper Respiratory Disorders

Upper respiratory infections (URIs) such as the common cold and coughs are treated with decongestants, cold preparations, and cough supressants (Julien, 1988). Numerous combination products have been formulated to treat the symptoms of minor URIs. These medications are composed of at least two of the following pharmacological groups: antitussives, expectorants, antihistamines, nasal decongestants, and bronchodilators (Julien, 1988). Combination products should be used only when multiple symptoms are present and the particular combination is designed to treat those specific symptoms. These symptoms must be severe enough to warrant treatment. Julien (1988) recommends additional guideliens in evaluating the potential use of combination cold products: (a) inclusion of no more than three drugs from the above-mentioned pharmacological groups, (b) each individual ingredient in the amount to provide safe and effective treatment of a specific symptom, and (c) consideration of the side effects of each drug.

Asthma, chronic bronchitis, and emphysema are identified as pulmonary or lower tract disorders. They are characterized by bronchospasms (Julien, 1988). Other symptoms include coughing, shortness of breath, wheezing, and chest tightness. Symptoms are often worse at night and may interrupt sleep.

Asthma is a common respiratory disease with a variety of characteristics. It is characterized by hyperresponsiveness of the trachea and airways to multiple stimuli, airway narrowing (source of wheezing, dyspnea, and cough), and airway inflammation. Attacks are triggered by exercise, irritants such as cigarette smoke, the common cold, and allergens such as pollen, dust, animal dander, and some foods (Busse, 1990). The airways narrow so that the amount of air entering and leaving the lungs is reduced. Bronchospasms, mucus formation, inflammation and edema of the lung contribute to airway obstruction (Busse, 1990; Pagliaro & Pagliaro, 1986).

Bronchodilators, drugs that expand the breathing passages in the lungs, are common in the treatment of asthma and other chronic lung obstructions. They relax tight bronchial muscles and dilate constricted airways. Bronchodilators reverse respiratory obstructions due to narrowed air passages and relieve and/or prevent spasms of the breathing passages in the lungs.

Mucolytics are used to treat chronic obstructive pulmonary diseases. They liquefy tenacious mucus secretions so that they are less sticky and thick. This reduces bronchiolar obstruction, improves ventilation, and facilitates removal of these secretions from the respiratory passages by coughing. These drugs relieve the abnormal, viscous mucus accumulation due to chronic lung diseases such as asthma, asthmatic bronchitis, tuberculosis, and complications of cystic fibrosis.

There are four groups of drugs used to treat asthma and other chronic pulmonary diseases. These include the xanthine (caffeine) derivatives such as theophylline, the adrenaline-like drugs, cromolyn and steroids. The xanthines have stimulant properties that may cause a child to act as though several cups of coffee were consumed. The adrenergic-like drugs are the growth area of asthma pharmacology. Even at normal doses, these drugs may produce nervousness and muscle tremors which may be manifested by shaking hands and deteriorating penmanship (Clayton & Stock, 1993). They may also act as stimulants in some children.

The corticosteroids are synthetics of hormones such as cortisone produced by the adrenal gland. They are not the same as the male steroid taken to increase strength. The dosage of steroids used to treat medical disorders exceeds the amount of cortisol secreted by the body daily.

Because they have antiinflammatory, metabolic, and immunosuppressant effects, steroids are used to treat multiple chronic, disabling medical disorders including collagen, endocrine, cardiovascular, and rheumatoid disorders; allergic states such as asthma and drug hypersensitivity reactions; acute leukemia; gastrointestinal diseases, and respiratory distress syndrome that are refractory to other treatment. They are most frequently used to treat accute flareups of inflammatory conditions such as arthritis and bronchial asthma, especially when aggressive, systemic therapy is required. They produce the best response when used to treat autoimmune diseases (Clayton & Stock, 1993). Steroids provide relief of symptoms, but do not change the course of diseases.

Steroids' usefulness stems from their antiinflammatory and antiallergic properties. They are the most effective antiinflammatories known and are most often used to treat local inflammatory conditions affecting the skin such as dermatitis and psoriasis (Phillips, 1988). As antiinflammatory drugs, the corticosteroids work by suppressing the immune system (Brewer, 1992). Hence, steroids are used to reduce rejection of transplants (Julien, 1988). Moreover, they quickly reduce pain and inflammation, allergic reactions, and asthma and colitis attacks (Phillips, 1988). Within days of treatment, steroids restore mobility and relieve the pain of arthritis (Phillips, 1988). However, the immunosuppressant effects of steroids also lower the body's resistance to infections and facilitate their spread (Julien, 1988).

Corticosteroids are among the most powerful drugs used in the treatment of allergies and asthma. Steroids prevent triggering inflammation of the airways and also reduce ongoing inflammation. Because several weeks are needed to achieve effectiveness, they are preventative medications only. Inhaled corticosteroids used in the treatment of bronchial asthma include **beclomethazone, flunisolide,** and **triamcinolone.**

Corticosteroids are also used to reduce inflammation and reduce the discomfort of inflammatory, ocular conditions, trauma to the eye and allergic disorders. Side effects from prolonged use include glaucoma; damage to the structure of the eye, including the optic nerve; cataract formation; and increased susceptibility to infections.

Steroids are safest when applied locally through inhalation, injection, or topical applications such as creams, but produce the same side effects irrespective of the means of administration. Topical steroids include **hydrocortisone, methylprednisolone, dexamethasone,** and **betamethasone.** The most common side effects associated with topical applications include local itching and irritation.

The side effects of steroids are directly related to length of treatment and dosage levels. Behavioral side effects coinciding with extended treatment include nervousness, insomnia, changes in mood or psychoses. Other side effects include lowered resistance to infection, indigestion, weight gain, loss of muscle mass and strength, mood changes, blurred vision, cataracts, diabetes, osteoporosis, and increased blood pressure. Fluid retention in the abdomen and cheeks producing the characteristic moon face is a serious concern. Children may gain 10 to 20 pounds when treated with steroids for JRA (Brewer & Angel, 1992). Steroids may retard growth which explains why they are drugs of last resort in the treatment of JRA. After chronic use, too rapid withdrawal of corticosteroids may result in acute adrenal insufficiency or a rebound effect (Friesen, 1987).

The following is a listing of drugs used to control epileptic seizures, to reduce the discomfort and other symptoms of arthritis, and to prevent or provide relief of respiratory illness, especially allergies and asthma. None cure the disorder. Trade names are listed first with the generic name in parentheses. Drugs are listed alphabetically by their generic names. Treatment comments are included in the right hand column. This listing is incomplete in both the number of drugs and their indications, side effects, and other treatment comments. Medical professionals and pharmacists, the most current *Physician's Desk Reference* (PDR) and other resources should be consulted for more complete information.

Anticonvulsants

Diamox **(acetazolamide)**	Diamox, a diuretic, is infrequently used as an anticonvulsant to great petit mal, grand mal, and focal seizures. Women with epilepsy associated with menstruation may be given this drug several days before the beginning of the menstrual cycle. Common side effects include diarrhea, increased frequency of urination, anorexia, and a metallic taste.
Tegretol **(carbamazepine)**	Tegretol is used to treat grand mal, psychomotor, and mixed seizures and may be used to treat seizures refractory to other anticonvulsants. It has also been used in the treatment of pain associated with tic douloureux. Investigational uses of Tegretol include bipolar affective and schizoaffective disorders, resistant schizophrenia, and rage reactions. Tegretol is chemically related to the TCAs so produces similar adverse effects and precautions, but is less sedating than other anticonvulsants. It is among the newest and most used anticonvulsants. Although the safety of this drug has not been established for children under 6, Tegretol is often preferred to phenobarbital in their treatment. The most frequent short-term side effects include blurred vision, nystagmus, drowsiness, dizziness, and nausea. Some tolerance to these side effects develops with continued use. Ataxia and nystagmus are associated with toxic levels of Tegretol. Several blood disorders are associated with the use of Tegretol (Friesen, 1987).
Klonopin **(clonazepam)**[4]	Klonopin is a primary drug of choice in the treatment of myoclonic seizures and is used to treat petit mal seizures and variants refractory to other drugs. In oral form, it is used to treat absence seizures in children. Nonapproved uses include control of grand mal, psychomotor and infantile spasm seizures. The effectiveness of Klonopin has been investigated for panic attacks. Its safety has not been established for long-term use with children. Common dose-related side effects of Klonopin include sedation and severe drowsiness in about 50% of epileptics and ataxia in about one third (Gadow, 1986). These effects usually disappear with continued use. Behavioral effects such as aggression, hyperactivity, irritability and difficulty concentrating occur in about 25% of patients (Friesen, 1987). Klonopin is removed slowly to reduce the likelihood of status epilepticus. If used alone with persons with mixed types of epilepsy, it may increase the frequency of grand mal seizures (Townsend, 1990).
Tranxene **(clorazepate)**[4]	Tranxene is used to treat anxiety and as an adjunct in the management of partial seizures. It It is contraindicated in children under 9.
Valium **(diazepam-IV)**[4]	Valium is used primarily to treat status epilepticus, but is not recommended for long-term control of epilepsy. Its most common side effects include drowsiness and ataxia. Grand mal seizures are exacerbated in some patients (Friesen, 1987).
Depakote **(divalprox sodium)**	Depakote is used to treat petit mal, grand mal, and myoclonic seizures primarily and may be used with complex partial seizures.
Zarontin **(ethosuximide)**[3]	Zarontin is used primarily in the treatment of petit mal seizures, but is also used for grand mal and psychomotor seizures. Its sole use in patients with mixed types of epilepsy may increase the incidence of grand mal seizures (Townsend, 1990). Tolerance develops with continued use. Zarontin is withdrawn if dyskinesias or psychiatric disorders occur (Friesen, 1987).
Peganone **(ethotoin)**[2]	Peganone is used to treat grand mal and psychomotor seizures. It is both the least toxic and least potent of the hydatoins.
Mesantoin **(mephenytoin)**[2]	Mesantoin is used to treat grand mal, psychomotor, focal, and Jacksonian seizures when less toxic anticonvulsants fail. It is the most toxic anticonvulsant. Its most common side effect is drowsiness.
Mebaral **(mephobarbital)**[1]	Mebaral is used to treat grand mal and petit mal seizures and moderate anxiety states. It is less likely to produce sedation or behavior problems than phenobarbital.
Gemonil **(metharbital)**[1]	Gemonil is used to treat grand mal, petit mal, myoclonic, and mixed types of seizures. It is usually combined with other anticonvulsants.
Paral **(paraldehyde)**	Paral is a sedative hypnotic used to treat seizures associated with emergency situations such as status epilepticus, tetanus, and drug poisoning.
Paradione **(paramethadione)**[5]	Paradione is used to treat petit mal seizures refractory to other anticonvulsants.

Luminal **(phenobarbital)**[1]	Phenobarbital is used to treat moderate anxiety states, insomnia, and status epilepticus. It is also used for the long-term management of seizures, especially grand mal, myoclonic jerking, and infantile spasms. It is the most commonly used barbituate in the treatment of epilepsy. Of all anticonvulsants, phenobarbital is least likely to produce serious side effects. Its most common side effect is sedation which necessitates monitoring school performance and achievement. Drowsiness usually subsides after several weeks of treatment. About 15% of young children may experience paradoxical CNS excitement or hyperkinetic-like syndrome (Friesen, 1987).
Milontin **(phensuximide)**[3]	Milontin is used in the treatment of petit mal seizures. Its sole use in patients with a mixed type of epilepsy may increase the incidence of grand mal seizures (Townsend, 1990).
Dilantin **(phenytoin)**[2]	Dilantin is used to treat grand mal and psychomotor seizures, grand mal seizures associated with neurosurgery or status epilepticus and to control seizures not caused by epilepsy (Julien, 1992; Bindler & Howry, 1991). It is contraindicated in the treatment of petit mal and seizures associated with hypoglycemia (Townsend, 1990). Fetal abnormalities have occurred when Dilantin was taken during pregnancy (Julien, 1992). At therapeutic levels, Dilantin is less sedating than barbituates. The side effects of Dilantin are related to the length of treatment, dosage or plasma levels, and mode of administration. The most common side effects of Dilantin include gingival hyperplasia which may result in dental problems, GI tract disturbances, and hirsutism. Overmedication with Dilantin produces a variety of CNS effects such as sedation, lethargy, nystagmus, ataxia, and diplopia. Behavioral indicators of toxicity include silliness, hyperactivity, drowsiness, hallucinations, and confusion. Increased frequency of seizures, confusion, slurred speech, vertigo, and hallucinations indicate more severe toxicity. Dilantin is discontinued if a skin rash occurs.
Mysoline **(primidone)**	Mysoline is used in the treatment of psychomotor, grand mal, and elementary focal seizures when other anticonvulsants were not effective. It is also used cautiously in the treatment of children with ADD and other disorders. It converts to phenobarbital in the body. Mysoline's primary side effect is drowsiness, especially early in treatment. Other reactions include ataxia, dizziness, skin rash, and GI distress (Malseed & Harrigan, 1989). It is often used with Dilantin.
Tridione **(trimethadione)**[5]	Tridione is used to treat petit mal seizures refractory to other anticonvulsants.
Depakene **(valporic acid)**	Depakene is used to treat petit mal seizures and as an alternative treatment of multiple seizures. It has investigational use in the management of other types of seizures, especially grand mal, myclonic, atonic, psychomotor, and infantile spasm seizures. It is among the newest and most used anticonvulsants, especially when other anticonvulsants are not effective. About 75% of epileptics respond favorably to Depakene (Julien, 1992). GI tract disorders, such as anorexia, nausea, vomiting, indigestion, and diarrhea occur often at beginning of treatment. Temporary hair loss, fine tremors, and sleep disturbance may also occur. There are few serious toxicities associated with Depakene.

Barbituates[1] produce selective depression of the CNS with relatively little toxicity (Julien, 1992). They are among the most frequently prescribed drugs for all types of epilepsy, but are most effective in the treatment of generalized seizures. Long acting barbituates are often combined with other anticonvulsants. Barbituates used in the treatment of epilepsy include Gemonil (**metharbital**), Mebaral (**mephobarbital**), Mysoline (**primidone**), and **phenobarbital.**

Because of their side effects, barbituates are used cautiously to treat children with behavior problems (Biederman & Steingard, 1991). Common side effects include overacivity, irritability, aggression, excitability, and a hangover effect. These effects may interfere with learning which is among the major disadvantages in using barbituates with children (Julien, 1992; Gadow, 1986).

Hydantoins[2] are used primarily in the treatment of generalized major motor seizures. They are also used in the treatment of psychomotor, elementary focal, and Jacksonian seizures. They are not CNS depressants nor do they interfere with normal sensory functioning. Adverse reactions include ataxia, confusion, slurred speech, diplopia, nystagmus, a skin rash, gingival hyperplasia, epigastric distress, and anemia (Malseed & Harrigan, 1989). Hydatoins used in the treatment of convulsive disorders include Dilantin (**phenytoin**), Mesantoin (**mephenytoin**), and Peganone (**ethotoin**).

Succinimides[3] are rarely used drugs prescribed for the treatment of petit mal seizures. In mixed seizure types, they increase the frequency of grand mal seizures. The most common side effects include nausea, gastric upset, anorexia, epigastric pain, hiccups, headaches, minor behavioral disturbances, and skin eruptions (Malseed & Harrigan, 1989). The side effects of Celontin and Milontin are similar to those of Zarontin, but are more likely to produce drowsiness. Succinimides used in the treatment of seizure disorders include Celontin (**methsuximide**), Milontin (**phensuximide**), and Zarontin (**ethusoximide**).

Benzodiazepines[4] are used to treat difficult-to-control seizures, particularly petit mal, myoclonic, and akinetic seizures. They work by controlling the spread of seizures (Clayton, 1987). Their use is periodically evaluated because of the possibility of drug-induced personality changes and learning problems (Julien, 1992). Common side effects include ataxia, drowsiness, blurred vision, and behavioral changes

(Malseed & Harrigan, 1989). Benzodiazepines used to treat seizure disorders include Klonopin (**clonazepam**), Tranxene (**clorazepate**), and Valium (**diazepam**).

Oxazolidinediones^5 are alternate drugs used in the treatment of petit mal seizures, but are rarely prescribed because of their side effects. Their most comon side effects include headaches, photophobia, diplopia, irritability, rash, drowsiness, hiccups, and abdominal pain (Malseed & Harrigan, 1989). The oxazolidinediones used to treat epilepsy include Paradione (**paramethadione**) and Tridione (**trimethadione**).

Non-Narcotic Analgesics

Tylenon, Datril **(acetaminophen)**	Tylenol and Datril are used in the treatment of fever and mild to moderate pain due to headaches, toothaches, influenza, and muscle skeletal distress. They are useful in the treatment of children and persons unable to tolerate aspirin. They are not associated with Reye's syndrome and cause fewer side effects than aspirin. Tylenol and Datril have analgesic and antipyretic actions similar to aspirin in equivalent doses, but are not effective as antiinflammatory agents. Therefore, they are not useful in the treatment of arthritis and acute inflammation. When used in recommended dosages, they are almost free of side effects. Hypersensitivity is often characterized by skin reactions (Friesen, 1987).
aspirin **(acetylsalic acid)**	Aspirin is most useful in the treatment of low intensity pain such as headaches and skeletal muscle discomfort; but, at higher doses, also reduces inflammation. Increased dosages of aspirin do not correspond to increased pain relief. Aspirin is the drug of choice in the treatment of inflammatory disorders, including all types of arthritis (Reiss & Melick, 1987). It is used to treate acute rheumatic fever. Described as the most important drug in the world, it is effective in treating about half the cases of RA with no additional medications (Phillips, 198). The most common side effects of aspirin involve GI upset such as epigastric distress, nausea, and vomiting. Toxicity is indicated by ringing in the ears, auditory and visual difficulties, mental confusion, thirst, and hyperventilation (Julien, 1992). Chronic use of aspirin may increase the chance of peptic ulcers (Friesen, 1987). The use of aspirin by children with chicken pox, influenza, or viral infections is associated with Reye's syndrome. Fatalities occur in about 40% of children with Reye's syndrome (Friesen, 1987). Aspirin is associated with increased bleeding during surgery, peptic ulcers, trauma, and blood disorders (Friesen, 1987). It is avoided when patients have peptic and other ulcers and is discontinued for at least a week before surgery.
Ascriptin **(acetylsalic acid)**	Ascriptin is sometimes prescribed to reduce the side effects of aspirin, especially those related to stomach upset.
Ridaura (oral gold/**auranofin**), Solganol (gold injection/ **aurothioglucose**), Myochrysine (gold injection/**sodium thiomalate**)	Arthritis has been treated with gold since the 1920s. Gold compounds are the most effective second-line drug in the treatment of mild to moderate RA when other treatments such as rest, physical therapy, and other drugs are not effective. It is not effective in the treatment of other forms of arthritis. Gold has been replaced by methotrexate as the primary second-line drug used to treat JRA. The first effect of gold, which occurs within two to four months of treatment, is reduction of morning stiffness (Brewer & Angel, 1992). Joint swelling, pain and tenderness are reduced after four to six months. Gold is not effective in reducing the high fevers of JRA (Brewer & Angel, 1992). About 10% of children stop taking gold because of intolerable side effects (Brewer & Angel, 1992). Side effects of gold include anemia, low white blood cell count, and liver function test abnormalities. Others include blood in the urine, easy bruising, sores in the mouth, skin rashes, and numbness of the hands and feet. There are few serius side effects, but if white blood cells are not made, the body becomes open to infections. Gold is added to treatment with NSAIDs, aspirin or corticosteroids, not substituted for it. If gold works, the other drugs may be eliminated. It is effective in about 50% of cases of RA (Brewer & Angel, 1992; DHHS, 1991). After five years of use, gold is effective only in 5 to 15% of persons with arthritis (DHHS, 1991).
Arthropan **(choline salicylate)**	Arthropan is a liquid salicylate that is used with children and others who have difficulty swallowing pills and capsules.

Dolobid **(diflunisal)**	Dolobid is an antiinflammatory analgesic used to reduce mild to moderate pain and osteoarthritis. It has little antipyretic effects.
Plaquenil **(hydroxychloroquine)**	Plaquenil is used primarily in the treatment of malaria. It is thought to work on the immune system to reduce pain, swelling, stiffness, and flare-ups of arthritis due to weather or illness (Brewer & Angel, 1992; NIA, 1990). It is orally administered for months before treatment effects become apparent. It reduces the need for steroids. Side effects of Plaquenil include low blood count, blood or protein in the urine, and abnormal liver function. Other side effects include diarrhea, headaches, loss of appetite, skin rash, and stomach pain. At high doses, it may damage the retina.
Mitrin, Rufen and OTCs such as Advil, Nuprin **(ibuprofen)** **(fenoprofen)**	These prescription and OTC drugs are used to treat mild to moderate pain and fever of RA, including JRA and osteoarthritis. They are not for use in home treatment of minor discomfort in children. These drugs produce aspirin-like antiinflammatory and analgesic effects at high doses. They produce side effects in the GI tract similar to, but less severe than those caused by aspirin. Common CNS side effects include headaches and dizziness. Skin rashes and itching may be fairly common.
Naproxin, Anaprox, Naprosyn **(naproxen)**	Naproxen is used to treat mild to moderate pain and inflammation of diseases such as JRA and RA. It is similar to ibuprofen, but requires a prescription. The side effects of naproxen involve the GI tract. They are similar to, but less severe than those associated with aspirin. Common CNS effects include headaches and dizziness. Skin rashes and itching may be fairly common. Information about side effects is derived from experience with adults. Ibuprofen, fenoprofen, and naproxen show analgesic, antipyretic, and antiflammatory effects. Their effectiveness is comparable to other non-narcotic analgesics and Darvon (Julien, 1992). They are used with caution in persons with peptic ulcers and bleeding disorders.
Indocin **(indomethacin)**	Indocin is used in the treatment of several types of active arthritis, including JRA. It reduces pain, stiffness, swelling, and tenderness of joints, but only 25% show significant improvement (Clayton, 1987). It is not used unless the arthritis is unresponsive to aspirin or safer nonsteroidal antiinflammatory drugs (Friesen, 1987). Indocin produces many side effects with chronic use incuding GI symptoms. CNS side effects occur frequently. They include headaches, dizziness, vertigo, and mental confusion (Friesen, 1987).
Abitrexate, Folex, Mexate **(methotrexate)**	Methotrexate is used primarily in the treatment of leukemia and other cancers. It is also used experimentally in the treatment of autoimmune disorders. It works on the immune system, reduces cell proliferation, and has antiinflammatory effects. **Methotrexate** is a rapid acting second-line drug used in low doses for the treatment of JRA. Because of lower doses, there are fewer side effects than found with cancer treatment. It does not retard the child's growth. It presents the same profile of side effects as other arthritis medications.
Depen, Curpimine **(penicillamine)**	Penicillamine is an orally administered drug that is used in conjunction with NSAIDs or other drugs to treat severe RA and JRA. Penicillamine works on the immune system. This drug is the least often used medication in the treatment of JRA and is only tried when others are not effective. After several months of treatment, it relieves joint pain, swelling, and stiffness. Side effects of penicillamine are very similar to those of injected gold.
Tolectin **(tolmetin)**	Tolectin is used in the treatment of osteoarthritis and rheumatoid arthritis, including JRA. It produces GI tract disturbances similar to but less severe than those of aspirin. Common side effects include headache, dizziness, skin rashes, and itching.

Antihistamines, Decongestants, and Antitussives

Bromarest, Chlorphed, Dimetane, Dimetapp Rolabromophen, Veltane **(brompheniramine)**	Antihistamine used in the treatment of rhinitis and allergy, including respiratory congestion with runny or stuffy nose and watery eyes. As an injection, brompheniramine is used to prevent allergic reactions to blood and plasma and to halt anaphylactic reactions (Bindler & Howry, 1991). It is contraindicated in asthma attacks.
Clistin **(carbinoximine)**, Rondec **(carbinoximine, pseudoephedrine)**	Antihistamine used to provide relief of allergic or vasomotor rhinitis. This drug acts as an antiemetic and has strong anticholinergic action.
Aller-Chlor, Chlor-Trimeton Chlormene, Histapan, Novahistine, Teldrin **(chlorpheniramine)**	Antihistamine used in the treatment of rhinitis and allergy. As an injection, it is used to prevent allergic reactions to blood and plasma and anaphylactic reactions (Bindler & Howry, 1991). This drug has antiemetic, antitussive, and some local anesthetic actions. It is contraindicated in acute asthma attacks.
Marezine **(cyclizine)**	Antihistamine and antiemetic used primarily to treat and prevent the nausea, vomiting, and dizziness of motion sickness and vestibular disorders.
Periactin **(cyproheptadine)**	Antihistamine and antipyretic used in the treatment of seasonal allergic rhinitis, conjunctivities, pruritus, and cold urticaria. It also relieves angiodema (the pronounced swelling of allergies from food and airborne allergens) and minor drug or serum reactions. Its unapproved uses include anorexia nervosa, somatrotropin deficiency, and Cushing's syndrome (Bindler & Howry, 1991). This drug has been used as an appetite stimulant in children (Clayton, 1987).
Pertussin 8-Hour, Romilars **(dextromethorphan)**	Antitussive that is also used in combination cough remedies such as Formula 44-D, Nyquill, Robitussin DM, and Vicks. This nonnarcotic antitussive (OTC) does not relieve pain or produce addiction.
Drammamine and others **(dimenhydrinate)**	Antihistamine and antiemetic used to prevent nausea and vomiting from motion sickness and to control dizziness and vertigo.
Benadryl, Benylin, Nordryl, Valdrene and others **(diphenhydramine)**	Antihistamine, antiemetic, and antivertigo drug used to prevent and treat symptoms of itching and swelling of skin from allergy and bug bites, milk allergies, vertigo, and motion sickness, and to suppress coughing and induce sleep. It relieves mild blood and transfusion reactions characterized by angioedema, urticaria, and pruritus. In combination products, it is used to treat URIs and colds. In topical form, it is used to treat pruritus and pain from sunburn, insect bites, and minor skin irritations.
Decapryn **(doxyamine)**	Antihistamine used to treat allergy symptoms and rhinitis. It is a component of cough and cold preparations.
Anti-Tuss, Robitussin, and others **(guaifensin)**	Antitussive that works as an expectorant to liquefy secretions in the lungs, promote productive coughing, and prevent the accumulation of tenacious airway secretions. It relieves dry, nonproductive coughing from minor throat and bronchial irritation of URIs.
Atarax, Vistaril and others **(hydroxyzine)**	Antihistamine, sedative, analgesic, and anxiolytic used to control pre-operative anxiety and to treat allergic pruritus, nausea, and vomiting of surgery and motion sickness. It is also used to treat emotional states characterized by anxiety, tension, and agitation. This drug may be combined with opiates and analgesics.
Bonine, Antivert **(mecilizine)**	Antihistamine and antinauseant used to control nausea, vomiting, and dizziness due to motion sickness and diseases of the vestibular system.
Tacaryl **(methdilazine)**	Antihistamine used to treat pruritus.
Allerest, Eye Drops, Clear Eyes, Privine **(naphazoline)**	Vasoconstrictor and nasal decongestant used to provide relief of nasal congestion or rhinitis. As an ophthalmic decongestant, it reduces redness in the eyes by decreasing swelling of the sclera due to minor eye irritations. Its use should be avoided in children.

Afrin, Dristan, Duration, Neosynephrine 12-hour **(oxymetazoline)**	Antihistamine and nasal decongestant used to relieve nasal congestion or rhinitis. It relieves a stuffy nose by reducing the swelling of the mucous membranes in the nose. Excess use may produce rebound stuffiness.
Neo-Synephrine, Alconefrin drops, Allerest Nasal, Coricidin Nasal Mist, Isophrin, Sinarest Nasal and others **(phenylephrine)**	Decongestant used as an oral inhalation to constrict bronchioles and relieve congestion. In a topically applied nasal form, this drug reduces congestion of the mucus membrane (stuffy nose) during an URI. In the form of eyedrops, it reduces redness of the eyes by reducing swelling of the sclera.
Decongestant P, Dimetapp, Propardine **(phenylpropanolamine)**	Widely used oral decongestant that is commonly found in OTC products such as Allerest, Contac, Sinutab, and Triaminic which provide relief of nasal congestion and rhinitis.
Phenergan and others **(promethazine)**	Antihistamine and antiemetic related to the phenothiazines used in the management of allergy and motion sickness. It is used pre-operatively for its sedative and antiemetic effects.
Sudafed, Novafed Afrinol, Neosynephrol **(pseudoephedrine)**	Alone, this drug is used as a nasal decongestant and vasoconstrictor to shrink swollen nasal mucus membranes and to allow the airways to open and sinuses to drain. It is combined with antihistamines, expectorants, and antitussives to treat allergies and provide symptomatic relief of colds and viral infections. Hypertension may occur at effective dosages.
Neo-Antegran, Allerest, Triaminic **(pyrilamine)**	Anthistamine used in combination cold remedies such as Allerest to provide symptomatic relief of allergic and vasomotor rhinitis. Because it produces sleepiness, this drug is also used in sleep aids such as Nytol and Sominex to treat insomnia.
Seldane **(terfenadine)**	Antihistamine used to relieve the symptoms of chronic allergic disorders, seasonal and perennial allergic rhinitis and dermatological disorders, including primary urticaria and eczema from histamine release and pruritus. It compares favorably in effectiveness with other anthistamines; but produces less drowsiness, sedation, and anticholinergic effects.
Tyzine, Murine Visine **(tetrahydrozoline)**	Nasal decongestant used to relieve nasal congestion and rhinitis. In the form of eyedrops, drug reduces redness of the eye by reducing swelling of the sclera from minor eye irritations. It produces significantly more side effects than other decongestants.
Temaril **(trimeprazine)**	Antihistamine used to treat pruritus.
Pyribenzamine PBZ **(tripelennamine)**	Anthistamine.
Actidil, Actifed **(triprolidine)**	Antihistamine used to provide symptomatic relief of allergic and vasomotor rhinitis. It has a rapid onset and few side effects. This drug may cause paradoxical irritability and excitation.
Otrivin drops, Sinutab, Neosynephrine 2 **(xylometazoline)**	Nasal decongestant at used to relieve stuffy nose.

Antihistamines

Mucomist **(acetylcysteine)**	This drug reduces the visocisity of purulent and nonpurulent secretions of the lungs from pneumonia, bronchitis, emphysema, tuberculosis, and pulmonary complications of cystic fribrosis. It enables removal of secretions by coughing, postural drainage, and mechanical means.
Proventil, Ventolin **(albuterol)**	Bronchodilator and adrenergic used to treat bronchospasms of asthma, brochitis, emphysema, and crystic fibrosis by dilating the smooth bronchial muscle and relieving obstructive bronchospasms. Common side effects include tachycardia, nervousness, tremors, and heaches. CNS excitement is common in children between 2 and 5 years (Bindler & Howry, 1991). Paradoxical airway resistance may develop with repeated, excessive use of inhaled albuterol (Friesen, 1987). Tolerance may develop with long-term use.
Aminophylline, Amoline, Somophyllin, and others **(aminophylline)**	Bronchodilator used for symptomatic relief of bronchial asthma and bronchospasms of bronchitis and emphysema. This drug is also used to treat status asthmaticus and congestive heart failure. It is meant to control asthma only under medical supervision.
Tornalate **(bitolterol)**	Bronchodilator, which metabolizes into colterol, used to treat bronchial asthma and to relieve the bronchospasms of bronchitis and emphysema. When compared to similar drugs, it has a longer duration of action with similar side effects.
Intal, Aarane, Opticrom and others **(cromolyn sodium)**	Anti-asthmatic and anti-allergy medication used in the prevention of severe bronchial asthma and bronchospasms and the prevention and treatment of allergic rhinitis, allergic ocular disorders and food allergies with symptoms such as runny nose, itching, and sneezing. It is also used to treat inflamed bowel diseases. It is among the safest drugs in the treatment of children. Cromolyn is an antiinflammatory drug, but has no direct bronchodilating effect. It may be used in the treatment of colds and exercise-induced asthma. It is a prophylactic whose effects do not become apparent until 4 weeks after the beginning of therapy (Friesen, 1987). There are few side effects of cromolyn, but those that occur often include local itching and burning. The most common side effects relate directly to the irritative properties of the inhaled powder, including bronchospasms, wheezing, cough, nasal congestion, and pharyngeal irritation (Friesen, 1987).
Lufyllin, Dilor, Neothylline **(diphylline)**	Bronchodilator used to treat acute bronchial asthma and the reversible bronchospasms of bronchitis and emphysema.
Vaponefrin, AsthmaHaler **(epinephrine/ adrenaline)**	Adrenergic used to treat reversible airway obstructions in allergies and acute asthma attacks and to provide systemic relief from anaphylaxis. It dilates and relaxes the smooth bronchial muscle to relieve the bronchospasms of acute and chronic asthma and reduce congestion within the bronchial mucosa. A cardiac stimulant, epinephrine may cause elevated blood pressure, cardiac stimulation, and other cardiac symptoms (Julien, 1988; Friesen, 1987). Paradoxical airway resistance may develop with repeated, excessive use of inhalation products (Friesen, 1987).
Teldral, Histadyl EC, Bronkaid, Bronkotabs, Mudrane **(ephedrine)**	Bronchidilator, vasodilator and nasal decongestant used to treat reversible airway obstruction due to mild forms of chronic pulmonary disease and to provide relief of nasal mucosal congestion. Ephedrine may cause cardiac symptoms such as elevated blood pressure and tachycardia (Friesen, 1987). CNS excitement is characterized by nervousness, occasional anxiety, and insomnia. Paradoxical airway resistance may develop with repeated, excessive use of inhalation products.
Bronkephrine **(ethylorephedrine)**	Bronchodilator used to treat reversible airway obstruction and relieve bronchospasms. It is often available in combination products. Cardiac symptoms include tachycardia. CNS excitement is chacterized by nervousness, occasional anxiety and insomnia. Paradoxical airway resistance may develop with repeated, excessive use of inhalation products.

Bronkephrine **(ethylnorephedrine)**	Bronchodilator used to treat reversible airway obstruction and relieve bronchospasms. I tis often available in combination products. Cardiac xymptoms include tachycardia. CNS excitement is characterized by nervousness, occasional anxiety and insomnia. Paradoxical airway resistance may develop with repeated, excessive use of inhalation products.
Arma-a-Med Isoetharine, Bronkometer, Bronkosol **(isoetharine)**	Bronchodilator used to treat reversible airway obstruction and relieve the bronchial smooth muscle. Cardiac symptoms include tachycardia. CNS excitement is characterized by nervousness, occasional anxiety, and insomnia. Paradoxical airway resistance may develop with repeated, excessive use of inhalation products. Tolerance may develop with prolonged or excessive use.
Medihaler-Iso, Isuprel, Norisodrine, Adrenaline, Sus-prine **(isoproterenol)**	Bronchodilator and adrenergic used to relieve bronchospasms, acute and chronic bronchospasms, bronchitis, and emphysema. It relaxes the smooth bronchial muscle and relieves bronchial constriction. Cardiac symptoms include tachycardia. CNS excitement is characterized by nervousness, occasional anxiety, and insomnia. Paradoxical airway resistance may develop with repeated, excessive use of inhalation product. Tolerance and rebound bronchospasms result from frequent use.
Alupent, Metaprel **(metaproterenol)**	Adrenergic and bronchodilator used to treat reversible airway obstruction in the management of asthma, to prevent exercise-induced asthma, or to enhance the therapeutic effect of theophylline. Cardiac symptoms include tachycardia. CNS excitement is characterized by nervousness, occasional anxiety, and insomnia. Paradoxical airway resistance may develop with repeated, excessive use of inhalation roducts. The safety of inhalation products wth metaproterenol is not established for children under 12. Side effects of the inhalation form include nervousness, tremor, and weakness. Tolerance can develop with long-term use.
Choledyl **(oxtriphylline)**	Bronchodilator used in the long-term treatment of bronchospasms of acute asthma, chronic bronchitis, and emphysema.
Adrenalin, Asthma Meter, Medihaler-Epi, Primatene Mist, Bronkaid Mist, Astj,amefrin, Duo-Medihaler **(phenyleprine with isoproterenol)**	Decongestant and bronchodilator. As a decongestant, it is a topically applied nasal preparation used to reduce congestion of URIs. As an oral inhalation, this drug causes constriction of the bronchioles and relieves congestion.
Bricanyl, Brethine, Brethaire **(terbutaline)**	Adrenergic and bronchodilator that dilates the smooth bronchial muscle. It is used to treat the symptoms of asthma and the bronchospasns of emphysema and chronic bronchitis. Cardiac symptoms include tachycardia. CNS excitement is characterized by nervousness, occasional anxiety, and insomnia. Paradoxical airway resistance may develop with repeated, excessive use of inhalation products. Its safety is not established for children under 12. Tolerance can develop from long-term use.
Theodur, Sl-Phyllin, Elixophyllin, Aerolate, Sustaire, Theolaire, Theobid, Theovent, Somophyllin, Slo-bid and others (over 50) **(theophylline)**	Bronchodilator used to treat bronchial asthma, status asthmaticus, and reversible bronchospasms of chronic bronchitis, emphysema and cystic fribrosis. It is available in combination with antitussives, expectorants, sedatives, and sympathominetics. There is a narrow band between therapeutic and toxic dosages. At therapeutic levels, theophylline may produce CNS excitation and seizures (Friesen, 1987). Theophylline is used cautiously with children. Toxicity is most often related to failure to take the medication, then double dosing (Steinmann, 1992). Common side effects of theophylline include nausea, loss of appetite, hyperactivity, and insomnia. Major side effects include persistent vomiting, vomiting blood, disorientation, and severe headache. Symptoms of overdose include nausea, vomiting, headache, tachycardia, dysrhythmias, hypotension, and hypoglycemia (Friesen, 1987).

Corticosteroids

Beconase, Vanceril and others **(beclomethazone aerosol)**	Steroid used to treat allergic rhinitis and asthma which are not responsive to traditional treatment and to treat steroid dependent asthma when it is necessary to reverse adverse effects or decrease the use of systemic steroids.
Cortelan, Cortone **(cortisone)**	Steroid used to treat severe seasonal and chronic bronchial asthma.
Decadron, Hexadrol, Heradrol **(dexamethasone)**	Steroid found in many combinations that is used to treat collagen and dermatologic diseases, allergies, acute leukemia and fetal respiratory distress syndrome. As an inhalation, it controls the symptoms of bronchial asthma and seasonal or perennial rhinitis when there is a poor response to traditional treatment.
Aerobid **(flunisolide)**	Steroid used to control the symptoms of bronchial asthma and seasonal or perennial rhinitis when there is a poor response to traditional treatment.
Cortisol, Cortef **(hydrocortisone)**	Steroid used to treat severe seasonal allergies. It is short acting and the least potent steroid used topically. It may be found in OTC products.
Medral, Wynacort **(methylprednisolone)**	Steroid used to treat opthalmic conditions such as allergic conjunctivitis as well as allergies and dermatological conditions.
Colisone, Cortan, Meticortin **(prednisone)**	Steroid used to treat collagen and dermatologic disorders, allergies, acute leukemia, RA, rheumatoid diseases, bursitis, and respiratory distress syndrome.
Cortalone, Delta-Cortef **(prednisolone)**	Steroid used to treat eye ailments, cancer, acute rheumatoid conditions, bronchial asthma, and post-operative dental inflammation.
Azmacort, Aristospan, Aristocort, Kenalog, Kenacort, Nasacort **(triamcinolone)**	Steroid used to treat collagen and dermatologic diseases, allergies, acute leukemia and other disorders. As an oral inhalation, it is used to treat bronchial asthma.

Appendix XI

Medications Commonly Used to Treat Children with Behavior Disorders: Antipsychotics, Anxiolytics, Antidepressants and Stimulants

Susan Vess
University of Southern Maine

OVERVIEW

In 1937, when a study was published on the effectiveness of d-amphetamine in the treatment of agitated children, the field of psychopharmacology began (Biederman & Steingard, 1991). Although more information about the usefulness of stimulants has been developed, there were few other major breakthroughs in pediatric psychopharmacology during the next 50 years (Biederman & Steingard, 1991).

BASIC CONSIDERATIONS

Psychotropic drugs such as antipsychotics, anxiolytics, antidepressants, and stimulants are medications designed to alter the behavior or emotions of children, adolescents, and adults with severe disturbances (Martin & Agran, 1988). These drugs change the individual's behavior in positive and negative ways, but do not cure the disorder. Although psychotropic medications are used in the treatment of many childhood disorders, relatively few children and adolescents are treated with drugs.

There are very few studies evaluating the long-term consequences of psychotropic drugs on children and their behavior, health, or learning (Schatzberg & Cole, 1991). Thus the effectiveness and safety of psychotropic medications with children and adolescents are almost never known prior to their introduction in treatment (Schatzberg & Cole, 1991). Most information about psychotropic drugs comes from adult-oriented research, clinical experience with adult patients, poorly formulated studies with children or anecdotes about the treatment effectiveness of a psychotropic drug with children and adolescents. Consequently, the FDA has not granted approval for the use of most psychoactive drugs with children or adolescents (Biederman & Steingard, 1991).

Despite the lack of FDA approval of these medications, psychotropic drugs are routinely prescribed. Crnic and Reid (1989) label the combination of medication with behavior management as the skills and pills approach to treatment.

Which particular drug is prescribed depends on the doctor's evaluation of how and how well a drug works to treat a particular disorder, what side effects accompany its use, health and other information about the patient, and the doctor's experience with the particular medication. The physician also considers the usual dosage of the drug, its route and schedule of administration, and its interaction with other drugs.

Because of the limited knowledge about the effectiveness and toxicity of medication in pediatric uses, psychotropic drugs should be prescribed only after other interventions such as psychotherapy and behavior management show limited or only short-term effectiveness (Biederman & Steingard, 1991). When prescribing these medications, the potential benefits must be constantly weighed against the long and short term risks of the drug.

Children tolerate higher dosages of psychotropic medications for their weight than adults tolerate because children's livers efficiently metabolize drugs (Schatzberg & Cole, 1991). Additionally, when drugs are used with accurately diagnosed disorders and at appropriate dosages, psychotropic medications produce small, but important, benefits (Biederman & Steingard, 1991).

Antipsychotics

Antipsychotics are indicated only for the treatment of childhood psychoses, but have been used to control behaviors such as severe agitation, aggression, self abuse, and insomnia associated with mental retardation and autism. They have been used to treat hospitalized nonpsychotic children and adolescents with angry, impulsive behavior (Schatzberg & Cole, 1991). Finally, these drugs have been tried in the management of Tourette's syndrome, Attention Deficit Disorder (ADD), and aggressive forms of Conduct Disorder (CD).

Children with autism and schizophrenia are frequently treated with antipsychotics, but demonstrate only modest improvement, especially when under 15 years (Schatzberg & Cole, 1991). In autistic children, antipsychotic medication is used to control stereotyped behavior and to reduce anxiety (Keltner, 1991).

In schizophrenic children, antipsychotic medication is used to reduce disordered thinking and to re-establish more normal behavior (Keltner, 1991). In both groups, these medications are used in the management of assaultive, aggressive, or self destructive behaviors (Keltner, 1991).

According to Keltner (1991), antipsychotics produce both neuroleptic and antipsychotic effects. Neuroleptic effects include sedation, emotional quieting, and psychomotor slowing. These effects are more relevant to autistic patients. Antipsychotic effects involve normalizing the patient's thoughts, moods, and behaviors (Keltner, 1991). These effects are more pertinent for schizophrenics.

Symptoms most responsive to antipsychotics include motor agitation, aggressiveness, tics, stereotypies, delusions, and hallucinations. Overactive, disorganized behavior in children may decrease (Schatzberg & Cole, 1991).

Children, adolescents, and adults are similar in their tolerance of antipsychotics and demonstrate similar side effects. Common short-term side effects of antipsychotic medication include drowsiness, weight gain, and increased appetite. Some also produce sedation and cognitive blunting which jeopardizes a child's opportunity to learn.

Additionally, all antipsychotics produce neurological side effects which are most often associated with the high potency medications. These side effects involve the extrapyramidal system and include dystonia, pseudoparkinsonianism, akinesias, and tardive dyskinesia.

To some extent, the specific array of side effects depends on whether a high potency versus a low potency drug was administered. High potency antipsychotics including Haldol and Stelazine produce neurological/extrapyramidal effects. Low potency antipsychotics including Thorazine and Mellaril produce side effects such as lowered blood pressure, drowsiness, and anticholinergic effects (constipation, dried mouth and nose, blurred vision, and difficulty urinating).

Because children show little improvement with antipsychotics and because these drugs produce important side effects, antipsychotics are used cautiously. As children grow into late adolescence, their schizophrenia becomes similar to that of adults. This results in similar effectiveness and safety considerations in the use of antipsychotic medications.

Anxiolytics

Anxiolytics treat anxiety and its symptoms primarily through generalized CNS depression (Townsend, 1990). Because they may produce behavioral inhibition, antianxiety drugs should be used cautiously in the treatment of children whose behavior is already inhibited (Biederman & Steingard, 1991). Four groups of drugs are used to treat anxiety: (a) barbituates, (b) antihistamines, (c) carbamates, and (d) benzodiazepines (Reiss & Melick, 1987). However, only antihistamines and benzodiazepines are used with sufficient frequency with children to merit discussion.

There is little information about the safety or effectiveness of antianxiety drugs in the treatment of children (Biederman & Steingard, 1991). Anxiolytics, especially the antihistamines, are used in the treatment of young children with poorly diagnosed insomnia and agitation (Biederman & Steingard, 1991). They are also used in the treatment of separation anxiety disorder, overanxious disorder, and avoidant disorder, the childhood anxiety disorders described in DSM III R. Anxiolytics are not used in the treatment of child sleep disorders such as night terrors and somnambulism.

Common short-term side effects of antianxiety medication include drowsiness, decreased mental acuity, and confusion at higher doses. These drugs should not be combined nor should they be stopped suddenly.

Antidepressants

Antidepressants are used along with psychotherapy in the treatment of affective disorders. However, their use with children is very limited. The antidepressants most often used with children are imipramine and amitriptyline. The side effects of these drugs most commonly involve their anticholinergic and sedative effects.

Persons who are seriously ill with disorders such as AIDS and cancer may take stimulants to treat their depression. Stimulants are also tried with persons who were not treated successfully with conventional antidepressants and psychotherapy.

Stimulants

CNS stimulants are used in the treatment of behavior problems such as impulsivity, inattentiveness, off-task behavior, and excess activity associated with ADHD in children and the mentally disabled and ADD in children and adults. They are the best studied and most understood drugs used in the treatment of childhood disorders. Stimulants are also indicated for the treatment of narcolepsy and obesity in adults.

The stimulant drugs most commonly used in the treatment of children are Ritalin and the amphetamines. Ritalin, Dexedrine, or Cylert have been used to treat 1 to 2% of children in elementary school and 80 to 90% of children with ADD (Pelham & Murphy, 1986). They are useful in treating ADHD in children over 5 years of age (Barkley, 1989). These drugs control the overt symptoms of ADHD, but should be used only in conjunction with other treatments such as behavior modification and social skills training. Not all children show improvements when administered stimulant medications.

D-amphetamine, Ritalin, and Cylert improve behavior and learning of 50–75% of children correctly diagnosed with ADHD (Julien, 1992). Learning may improve with stimulant medication because the child's attention span is improved. However, stimulants are insufficient to produce normal academic and social functioning.

Ritalin and d-amphetamine produce their effects within 30 to 60 minutes and reach their peak effectiveness in 1 to 3 hours after administration (Biederman & Steingard, 1991). Several daily dosages are required of these two short-acting drugs. Of the three, Cylert is somewhat less effective and less safe; however, it may be administered in a single dose each day (Schatzberg & Cole, 1991). Its effectiveness may not be apparent for several weeks (Biederman & Steingard, 1991).

Current practices suggest that children, especially those with severe ADHD or CD, should be medicated throughout the week and during vacations (Barkley, 1989). While drug holidays allow evaluation of the usefulness of stimulant medication, interruptions in treatment may have negative consequences for the child's relationships with family and peers and for learning outside school.

Stimulants are used cautiously with psychotic children and persons with Tourette's syndrome or motor tics because these drugs increase the likelihood of a tic disorder, even when medication is discontinued (Biederman & Steingard, 1991). They are contraindicated in the presence of anorexia, insomnia, and other disorders. Stimulants may aggravate anxiety in some patients. They may also inhibit the metabolism of anticoagulants, anticonvulsants, and tricyclic antidepressants (TCAs).

The most commonly reported side effects of stimulants are insomnia and delayed sleep onset due to late afternoon or early evening administration of the drug. Others include tremors, weight loss, slight suppression of growth rate, nervousness, mild increases in heart rate and blood pressure, and changed mood with irritability, weepiness or oversensitivity. Some may aggravate seizure disorders (Friesen, 1987). There may be a rebound effect or transient behavior problems with discontinuation of stimulant medication (Biederman & Steingard, 1991). Prolonged use may result in psychological or physical dependence.

Psychoactive drugs are widely prescribed in the treatment of the mentally disabled, especially hospitalized adults with severe, antisocial, debilitating behavior (Crnic & Reid, 1989). Antipsychotic medications such as Thorazine, Navane, and Haldol are used to control aggression, destructiveness, hyperactivity, and antisocial behavior (Crnic & Reid, 1989). Stimulants are commonly prescribed to treat moderately and mildly disabled children enrolled in the public schools to improve their learning, attending, impulse control, and activity level (Crnic & Reid, 1989). Finally, anticonvulsants are administered to the mentally disabled to control behavior problems despite no evidence that these drugs improve cognition or behavior (Crnic & Reid, 1989). A large percentage of mentally disabled who receive anticonvulsants show no evidence of seizure activity (Crnic & Reid, 1989).

Information about psychotropic medications is listed in chart form for convenient access. The trade name appears first, then the generic name in parentheses. Drugs are ordered alphabetically by their generic names. Additional information is located in the treatment comments column. Medical professionals such as doctors and pharmacists and other resources such as the latest *Physician's Desk Reference* (PDR) should be consulted for more complete information about a disorder and its medical treatment.

Psychoses

Thorazine **(chlorpromazine)**[2]	Thorazine is used to treat acute and chronic psychosis such as schizophrenia, to control children with agitated or very excited behavior and excessive motor activity, and to manage children with severe behavioral problems such as explosiveness, hyperexcitability, or combativeness (Townsend, 1990; Clayton, 1987). Because of its sedative effects, it may be used with the severely or profoundly mentally disabled or to treat those who are violent or agitated (Thomas, 1988). It is the most well-known and well-researched of the phenothiazines (Julien, 1992). There is a low incidence of extrapyramidal effects with Thorazine.
Catapres **(clonidine)**[3]	Catapres is an antihypertensive drug used to treat severe Tourette's syndrome, including explosive violent behavior (Schatzberg & Cole, 1991). Its side effects include dry mouth, constipation, sedation, and hypotension.
Haldol **(haloperidol)**[1]	Haldol is a tranquilizer used to treat agitated states of psychosis in children and adults. Other uses include control of motor and vocal tics of Tourette's syndrome as well as hyperactivity and severe behavior problems of children (Townsend, 1990). It is also prescribed in the short-term management of ADD (Bindler & Howry, 1991). Although showing limited effectiveness in the treatment of children with autism, Haldol is used with autistic children with serious management problems to decrease maladaptive behavior and to increase discriminative learning (Schatzberg & Cole, 1991; Perry & Meislas, 1988). It is used to treat autism with alternating hyperactivity and hypoactivity. It reduces high levels of stereotypies and increases orienting reactions in children who previously showed little orientation (Perry & Meislas, 1988). It has been used in the treatment of persons not responding to phenothiazines (Julien, 1992). Haldol may cause extrapyramidal side effects (Martin & Agran, 1988).
Inderol **(propranolol)**[3]	Inderol, a beta blocker, has not been approved for use with children. However, its usefulness in the treatment of severe aggressive and self injurious behaviors, schizophrenia, anxiety disorders, and Tourette's syndrome has been investigated (Biederman & Steingard, 1991). Reduction of explosive behavior in children and adolescents as well as aggression in the mentally disabled have been reported (Biederman & Steingard, 1991). Its most common side effects include nausea, vomiting, constipation, and mild diarrhea.
Mellaril **(thioridazine)**[2]	Mellaril is used to treat hyperkinesis, combativeness, aggression, and severe behavior problems in children (Bindler & Howry, 1991; Townsend, 1990). It is among the most frequently used antipsychotics with children (Gittelman & Kanner, 1986). It may be used to control aggression and hostile and self injurious behavior in the mentally retarded (Martin & Agran, 1988). Because of its sedative effects, Mellaril may be used with the mentally disabled or profoundly retarded (Thomas, 1988). This tranquillizer reduces psychomotor agitation and tension from psychoses and neuroses (Clayton, 1987). It has the least extrapyramidal effects of the phenothiazines.
Stelazine **(trifluoperazine)**[2]	Stelazine is used to treat anxiety, tension, and agitation due to psychoses. It may control head banging, self injury, hyperactivity, and assaultiveness in the mentally disabled (Thomas, 1988). The patient is monitored for extrapyramidal effects, especially when taking large doses. However, it produces less sedation, blurred vision, and hypotension than other phenothiazines.

Butryophenones[1] are similar to phenothiazines, but work more quickly. In children, they frequently produce the extrapyramidal effects of akathisia and dystonia (Pagliaro & Pagliaro, 1986).

Phenothiazines[2] which include both high and low potency medications, are the oldest, most studied and most widely used group of antipsychotics with both adults and children.

Other drugs[3] have been used in the management of psychosis and other disorders frequently treated with antipsychotic medications.

Anxiety

Xanax **(alprazolam)**[2]	Xanax is used to treat the symptoms of anxiety and anxiety with mild symptoms of depression and panic disorders. It is not approved by the FDA for treatment of depression, but some doctors find the drug helpful. Xanax is contraindicated in children under 18 (Townsend, 1991).
Librium **(chlordiazepoxide)**[2]	Librium is a tranquilizer used to treat mild to moderate anxiety and tension. It has been used along with psychological treatment with adolescents and young adults showing anxiety disorders (Martin & Agran, 1988). This drug has antiepileptic properties.
Tranxene **(clorazepate)**[2]	Tranxene is used in the treatment of anxiety and epilepsy. It is contraindicated in children under 9 (Townsend, 1990).
Valium **(diazepam)**[2]	Valium is a tranquilizer and anxiolytic used to treat mild to moderate anxiety disorders and tension, perhaps Generalized Anxiety Disorder (GAD), skeletal muscle spasms of cerebral palsy, convulsive disorders and status epilepticus. Its effectiveness in the treatment of night terrors has been investigated (Townsend, 1990). It has been used along with psychological treatment with adolescents and young adults showing anxiety disorders (Martin & Agran, 1988). This drug has antiepileptic properties.
Atarax, Vistaril **(hydroxyzine)**	This antihistamine is used in the treatment of anxiety, especially from allergic reactions due to pruritus or asthma and to produce sedation prior to surgery.

Antihistamines[1] have been used to treat anxiety because of their sedative effects. They are successful in the treatment of anxiety that accompanies skin disorders with severe itching (Reiss & Melick, 1987). Two antihistamines used to treat anxiety are Atarax (**hydroxyzine chloride**) and Vistaril (**hydroxyzine pamoate**). These drugs are safe and produce minimal negative reactions so are often used to treat children as a preoperative sedative and to relieve itching (Malseed & Harrigan, 1989).

Benzodiazepines[2] are used in the treatment of anxiety and epilepsy, as muscle relaxants and as an aid to sleep. These drugs, especially Librium, Valium, and Xanax are the anxiolytics used most often with children. They may result in increased activity or aggravate behavior disorders, especially in children with ADHD (Schatzberg & Cole, 1991).

Benzodiazepines are relatively safe drugs, unless combined with other substances. About half of patients treated with benzodiazepines experience symptoms of withdrawal such as nervousness, insomnia, and loss of appetite when these drugs are stopped.

Benzodiazepines are CNS depressants whose individual derivatives have their effects on different sites in the brain. Therefore, specific drugs are used to treat specific types of disorders.Benzodiazepines are often grouped on the basis of their clinical use: (a) anticonvulsants (**diazepam, clonazepam,** and **clorazepate**), (b) antianxiety, and (c) hypnotics (**flurazepam, triazolam,** and **tomazepam**).

Affective Disorders

Amitrill, Elavil, Endep, and others **(amitriptyline)**	This drug is used to treat major depression, especially with anxiety. It has also been used to treat severe chronic depression in children with normal intelligence and may be used to treat hperactivity (Martin & Agran, 1988). It has been investigated in the control of chronic pain and the prevention of migraines. Nonapproved uses in children include treatment of anorexia and bulimia, ADD, enuresis, and pruritus in cold urticaria.
Wellbutrin **(bupropion)**[2]	Wellbutrin is used to treat major depression in patients who did not respond adequately to or could not tolerate other antidepressants (Townsend, 1990). Wellbutrin has been tried successfully in the treatment of children with ADD (Julien, 1992; Schatzberg & Cole, 1991). Its safety in children under 18 has not been established. Persons with bulimia or anorexia show a high incidence of seizures with this medication (Townsend, 1990). The side effects of Wellbutrin include behavior stimulation, anxiety, restlessness, tremor, and insomnia.
Anafranil **(clomipramine)**[1]	Anafranil is not FDA approved because it seems to increase the risk of seizures. It has been found effective in the treatment of obsessive compulsive disorder (OCD) in both children and adolescents (Schatzberg & Cole, 1991). This drug has been used in Europe to treat depression and OCD.
Norpramine, Pertofane **(desipramine)**[1]	This drug has been used to treat major depression in children and adults. Its effectiveness in the treatment of ADD in children is under investigation (Townsend, 1990).

Prozac **(fluoxetine)**[2]	Prozac is used to treat depression, especially when the depression is mild or the person is an outpatient (Julien, 1992). Its effectiveness in the treatment of exogenous obesity is under investigation. Prozac has been tried in the treatment of persons with OCD, bulimia, and panic and anxiety disorders (Julien, 1992). Its safety in children has not been established. Prozac is now the most widely prescribed antidepressant (Julien, 1992). The side effects of Prozac include nervousness, anxiety, sexual dysfunction, motor restlessness, and muscle rigidity. It lacks the anticholinergic or cardiac effects of the TCAs.
Tofranil **(imipramine)**[1]	Tofranil, the first antidepressant identified, is used in the treatment of major depression with melancholia or psychotic symptoms. It is the only TCA approved for use with children and the most frequently studied TCA with children. Tofranil has been FDA approved only for the treatment of enuresis in disabled and nondisabled children. Apparently, its success in treating enuresis rests on its anticholinergic effects. Behavior treatment of enuresis is often more effective and results in fewer relapses (Schatzberg & Cole, 1991). Tofranil soothes adult panic attacks (Gittelman & Kanner, 1986). It has been used to treat depression in children who are not mentally disabled. This drug is the most studied TCA in the treatment of childhood depression and is sometimes used to treat separation anxiety disorders (Thomas, 1988; Gittelman & Kanner, 1986). Tofranil's effectiveness in the treatment of ADD in children is under investigation (Bindler & Howry, 1991; Townsend, 1990). Additionally, high dosages of Tofranil have been tried in the treatment of school phobia (Biederman & Steingard, 1991).
(Lithium carbonate)	Lithium is used to treat bipolar disorders. Its usefulness in the treatment of children with a mixed bipolar disorder, aggressive behavior, and hyperactivity with psychotic or neurotic components has been investigated (Townsend, 1990). Lithium may be useful in the treatment of resistant depression, OCD, and some schizophrenia (Julien, 1992). There is little documentation of lithium's usefulness in treating children, but it has been tried in the treatment of children with ADD, CD, anorexia, and schizophrenia when family members show a history of manic depression. It may also be used to treat a childhood behavior disorder that includes emotional lability and aggression when family members demonstrate bipolar or major depressive disorders. It is used to treat aggression, hyperactivity, or self-injurious behavior in mentally disabled children (Thomas, 1988). The side effects of lithium are related to plasma concentrations. They include nausea, vomiting, diarrhea, tremor, and increased output of urine. These side effects are the same in persons of all ages, but children may tolerate lithium better than adults. The therapeutic dose of lithium is very close to the toxic dosage, but the safety and adequacy of dosage is easily monitored by measuring serum lithium levels in the blood (Biederman & Steingard, 1991; Schatzberg & Cole, 1991) As the concentration level of lithium increases, toxic effects such as fatigue, muscle weakness, slurred speech, and tremors also increase. The use of lithium may result in serious complication when combined with electroshock therapy or Haldol. Infrequently, persons not responding well to or tolerating lithium have been treated with anticonvulsants, especially Tegretol and Depakane (Julien, 1992).

Tricyclic Antidepressants[1] (TCAs) are used primarily in the treatment of major depression in adults, but they have been used for over 30 years to treat depression in both adults and children (Carlson, 1988). They are the most widely studied of the antidepressants for use with children (Kazdin, 1989). These drugs, especially imipramine, are effective when they reach therapeutic levels of plasma concentration.

The TCAs have been found effective in the treatment of enuresis (imipramine), ADHD, childhood depression and juvenile anxiety disorders (Biederman & Steingard, 1991). These drugs, especially imipramine and desipramine, are used to treat children with ADHD for whom stimulants are contraindicated or for whom ADHD is combined with a significant mood disorder (Barkley, 1989). They have been used in the treatment of anorexia, bulimia, OCD, panic disorder, chronic pain, migraine headaches, post-traumatic stress disorder, and peptic ulcers (Julien, 1992). Finally, the TCAs may also be useful in the treatment of Tourette's syndrome and anxiety disorders (Biederman & Steingard, 1991).

Generally, TCAs are slow-acting drugs which require 4 to 8 weeks of administration to demonstrate effectiveness. Children with enuresis or ADHD respond within days to TCAs, but take several weeks to respond to TCAs in the treatment of mood disorders. Children are treated with TCAs for 3 to 6 months (Martin & Agran, 1988).

The most frequently administered TCAs are **imipramine, desipramine, amitriptyline,** and **nortriptyline.** Of these, amitriptyline produces the most side effects, especially sedation. A particular TCA is selected because of its effectiveness, side effects, and duration of action (Julien, 1992). Of the TCAs, the most is known about the effectiveness and safety of imipramine in the treatment of children. In addition to treating enuresis, TCAs may be effective in the treatment of children with major depression (Biederman & Steingard, 1991).

The effectiveness and side effects of TCAs when used with children are similar to those found with adults (Biederman & Steingard, 1991). The most common side effects relate to the TCAs' anticholinergic effects such as constipation, dry mouth and nasal passages, blurred vision, and urinary hesitancy. Because of limited salivation due to anticholinergic effects of TCAs, some children may experience tooth decay. Other side effects include increased sensitivity to sun light, dizziness on standing quickly, increased heart rate, increased sweating, weight gain, and drowsiness. However, the effectiveness and safety of these drugs is often unpredictable with children.

TCAs lower the seizure threshold so should be used with caution in the treatment of epileptics. Because they decrease their metabolism, combining anticonvulsants or antipsychotics with TCAs may increase their toxicity (Biederman & Steingard, 1991). TCAs may also exacerbate the psychotic and manic symptoms of schizophrenia and mania (Biederman & Steingard, 1991). There is little information about the safety and effectiveness of **Second Generation (Atypical) Antidepressants**[2] with children.

Monamine Oxidase Inhibitors (MAOIs) preceeded TCAs in treatment of depression. Forms that are effective and less toxic are being developed (Julien, 1992). There is minimal information on the safety and effectiveness of MAOIs in the treatment of children. However, they may be useful in the treatment of major depression, CD, childhood schizophrenia, autism, phobic anxiety states, and OCD.

The use of MAOIs is limited by their side effects, especially interactions with drugs such as cold medications and nasal decongestants and foods with tyramine such as aged cheese, red wine, aged meat (sausages and corned beef), aged fish (pickled herring), broad beans, etc. These interactions may produce a hypertensive crisis, including a severe increase in blood pressure, severe headaches, increased heart rate, and palpitations. Hypertensive crisis may lead to stroke, other severe problems, and even death. Because of the above interactions and because they interact with stimulants, MAOIs are rarely used with children.

Stimulants

Dexedrine **(dextroamphetamine sulfate)**	Dexedrine is used in the treatment of ADHD, narcolepsy, and exogenous obesity. It is used cautiously with psychotic children and persons with Tourette's syndrome.
Pondimen **(fenfluramine)**	Pondimen is used in the treatment of exogenous obesity. An investigational use includes treatment of autistic children with elevated serotonin. It is a promising drug in the treatment of autism to improve the behavior of children with severe management problems. Autistic children with IQs over 40 and extreme agitation demonstrate greater social awareness, communication, and cognitive functioning and show less hyperactivity, sensorimotor symptoms, irritability, temper tantrums, aggression, and self mutilation with Pondimen (Biederman & Steingard, 1991). The safety of Pondimen has not been established for children under 12. This drug reduces appetite with little behavioral stimulation.
Desoxyn **(metamphetamine)**	Desoxyn is used to treat ADHD, narcolepsy, and exogenous obesity.
Ritalin **(methylphenidate)**	Ritalin is used to treat narcolepsy and ADHD. It is contraindicated in persons with motor tics or diagnosis/family history of Tourette's syndrome and severe depression. Its safety on children under 6 has not been established. Ritalin may lower the seizure threshold (Reiss & Melick, 1987).
Cylert **(pemoline)**	Cylert is used to treat ADHD. Investigational uses include narcolepsy and excessive daytime sleepiness. It is contraindicated in persons with Tourette's syndrome or history of tics. Cylert is chemically different from Ritalin and Dexedrine and produces less CNS stimulation. It is sometimes associated with liver abnormalities.

ANNOTATED BIBLIOGRAPHY

Gelenberg, J. A., Bassuk, E. L., & Schoonover, S. C. (Eds.). (1991). *The practitioner's guide to psychoactive drugs* (3rd ed.). New York: Plenum.

This volume is particularly useful in many ways. First, this book is a very readable and complete discussion of the major psychological disorders. Second, it provides background on other topics such as the use of medications with children and geriatric populations. Third, it describes the various treatments used with a particular disorder in addition to medication.

Julien, R. M. (1992). *A primer of drug action* (6th ed.). New York: W. H. Freeman.

Julien, R. M. (1988). *Drugs and the body.* New York: W. H. Freeman.

These two books are very useful in describing how the body functions and various physical and psychological disorders. They also explain how drugs work and provide basic information about categories of medication. These are only two of Freeman's excellent books about drugs and psychological disturbances.
